**090187** NEW MODEL FOR ELECTRON MOVEMENT IN A THICK FILM RESISTOR AND ITS APPLICATION TO ANALYSIS OF THE STRUCTURE AND CONDUCTION MECHANISM IN THESE RESISTORS. A new model has been developed to explain the strain behaviour of thick film resistors. In this model, the electron moves in a meandering way through the resistor. By measuring the strain sensitivity and applying the meander model on it, information is obtained about the structure of the thick film resistor and the strain sensitivity of the micro-electron paths in the resistor. The latter can be a useful tool in testing models that describe conduction mechanisms in thick film resistors. In this research, measurements on the strain sensitivity of thick film resistors were made using a

four-point-bending bridge and the four-point-resistance measurement was made using special probes. Long, narrow enamel-coated steel substrates were used to enhance the accuracy of the measurements. (Author abstract) 14 refs.

**090188** QUALITY AND QUANTITY IN THICK-FILM RESISTORS. Thick-film resistors can be produced in quantity as well as in quality, using well-planned techniques. The effective and economical fabrication of thick-film resistors requires the use of design methods and production controls adequate to obtain high yields. To appreciate the basic problems involved, it is convenient to think of thick-film resistors as one-way potentiometers, in which it is possible to increase the value up to a certain point, but not to decrease it under ordinary conditions. The goal is therefore to obtain a distribution of resistor values after the firing process in such a way that the resulting values are at or below the maximum value allowed by the circuit design, but above the minimum value, to avoid excessive trimming. This goal requires both effective design techniques and process controls.

Sargent, Jerry E. (Sargent & Sargent, Colorado Springs, CO, USA). *Electron Packag Prod* v 28 n 1 Jan 1988 p 70-72.

**090189** JUST A TRIM, PLEASE. Precision trimming with a multiple-trim sequence can help manufacturers keep pace with rapidly evolving hybrid technology and increasing circuit density. Since constraints on trimming increase as the geometry of hybrid resistors shrinks, improved trimming techniques are crucial. With smaller resistors, factors such as geometry, topography and heat dissipation from trimming take on greater significance. A trim technique is introduced that helps overcome problems in large resistors. In this article, the making of a 0.030-in.-square, eight-resistor network illustrates this trim procedure. All the resistors in the network are matched to within 0.03%.

Couch, Bruce (Teradyne Inc, Boston, MA, USA). *Circuits Manuf* v 28 n 4 Apr 1988 p 49-50.

**090190** PERCOLATION NETWORK FOR THICK RESISTIVE FILMS. A random resistance network with double percolation has been proposed for thick resistive films (TRFs). This network has been developed on the basis of our two previous models of these films' structure and conduction mechanism. Two types of resistances: (i) constriction resistance, and (ii) barrier resistance for thermally activated tunneling, have been included. Monte Carlo calculations of the network resistance ( $R_{RN}$ ) vs temperature ( $T$ ) have been presented using the data found for RuO<sub>2</sub>-based TRFs. It has been shown how the network parameters: volume fraction of conducting component,  $v$ , ratio of diameters of insulating and conducting particles,  $\chi$ , ratio of barrier resistance to constriction resistance,  $r$ , and probability  $p_1$  of the bond occupancy by constriction resistance, influence the shape of the characteristics,  $R_{RN}$  vs  $T$ . It has been found that proper choice of large  $r$  values together with relatively small  $v$ ,  $\chi$  and  $p_1$  values results in flat  $R_{RN}$  vs  $T$  characteristics which are consistent with the observation for real TRFs. An interpretation based on the deterministic resistance network has been given. (Edited author abstract) 21 refs.

**090191** PHASE EQUILIBRIA IN THE RuO<sub>2</sub>-Bi<sub>2</sub>O<sub>3</sub>-PbO SYSTEM. The proposed Bi<sub>2</sub>O<sub>3</sub>-RuO<sub>2</sub> phase diagram is shown. The melting temperature of the eutectic composition (around 80 percent Bi<sub>2</sub>O<sub>3</sub>) is 745°C, some 15 K higher than the temperature of the  $\alpha$ -Bi<sub>2</sub>O<sub>3</sub> to  $\delta$ -Bi<sub>2</sub>O<sub>3</sub> phase transition. At 950°C, Bi<sub>3</sub>Ru<sub>3</sub>O<sub>11</sub> transforms into Bi<sub>2</sub>Ru<sub>2</sub>O<sub>7</sub>. The ternary phase diagram (subsolidus) of

$\text{RuO}_2\text{-Bi}_2\text{O}_3\text{-PdO}$  is also presented. There is no ternary compound. The tie lines are between  $\text{PdO-Bi}_2\text{Ru}_2\text{O}_{11}$  and  $\text{Bi}_2\text{Ru}_2\text{O}_{11}\text{-Bi}_2\text{PdO}_4$ . The results indicate that there is no reaction between the conductive phase in thick film resistors (either  $\text{RuO}_2$  or bismuth ruthenate) and  $\text{PdO}$  during the firing of thick film circuits. 11 refs.

**090192 NITROGEN-FIREABLE RESISTORS; EMERGING TECHNOLOGY FOR THICK-FILM HYBRIDS.** A nitrogen-fireable base-metal thick-film resistor system compatible with copper conductors has been developed. A lanthanum hexaboride conductive phase is used to make resistor compositions in the range  $10\ \Omega/\text{2b-}10\ \text{k}\Omega/\text{2b}$ , and doped tin oxide is used as the conductive in the  $10\ \text{k}\Omega/\text{2b-}1\ \text{M}\Omega/\text{2b}$  resistance range. A transfer program to move this technology from the research laboratory to full commercial availability is underway. The environmental stability of 44 lots made in pilot, prototype, and manufacturing scale runs have been evaluated and confirm lot-to-lot reproducibility. Lanthanum boride members show good environmental stability under all conditions. Doped tin oxide members are humidity-sensitive and require encapsulation. When encapsulated with an organic material, all grades show maximum changes of less than 1% after 1000 h of exposure to  $85^\circ\text{C}/85\%$  relative humidity. 20 refs.

**090193 KINETICS OF THIN FILM RESISTOR STABILISATION.** Thin film resistors are manufactured by photolithography methods, using a nickel-chromium alloy vacuum deposited on a ceramic substrate. In order to stabilize the resistors, a high temperature heat treatment in an air furnace is undertaken, during which the resistors are partially oxidized. It was found that the extent of reaction can be expressed as  $p=6 \times 10^4 \exp(-7400/T) t^{1/3}$ . A temperature of  $325^\circ\text{C}$  is recommended for practical applications. It involves a 30% resistance increase after an hour, while standard deviation is less than 2%. (Author abstract) 12 refs.

**090194 TA-Si-C HIGH RESISTIVITY THIN FILMS FOR THERMAL PRINTING HEADS.** Ta-Si-C thin films have been developed for thermal printing heads, and the effect of composition on the film properties has been studied. The results show that: (1) when Ta-Si-C thin films are formed, the composition of the film does not agree with the target composition; (2) the addition of carbon to Ta/SiC mixtures suppresses recrystallization during high-temperature treatment; (3) excellent characteristics are achieved with thermal printing heads using Ta-Si-C thin films formed using a target with more than 20% carbon in a Si/C mixture; and (4) irreversible resistance changes are very small in thermal printing heads containing more than 20% carbon when external heat is applied. These findings indicate that Ta-Si-C is an excellent material for use in thermal printing heads. 9 refs.

**090195 CHARACTERIZATION, EVALUATION,**

**AND COMPARISON OF LASER-TRIMMED FILM RESISTORS.** Methods for predicting the performance of laser-trimmed film resistors taking into account the properties of the heat-affected zone (HAZ) are discussed. A figure of merit based upon a sensitivity function called HAZ sensitivity,  $\text{SHAZ}$ , is introduced which is useful for determining aging and temperature effects of an arbitrary film-resistor geometry with an arbitrary trim strategy.  $\text{SHAZ}$  is also shown to be useful in predicting performance of ratio-matched resistor structures. The proposed technique is incorporated in FIRE, a Fortran program for analyzing arbitrary film structures with a given trim path. Examples using popular resistor geometries and trimming algorithms illustrating the use of the suggested figure of merit are presented. The performances of these structures are compared quantitatively. 13 refs.

**090196 NEW LASER-TRIMMED FILM RESISTOR STRUCTURES FOR VERY HIGH STABILITY REQUIREMENTS.** The drift with time and/or temperature of laser-trimmed film resistors limits the effective accuracy attainable from laser-trimmed resistor circuits. This accuracy is dependent on the geometries of the film resistors and on the trimming process. Novel film resistor structures that practically and significantly improve the effective ultimate accuracy attainable with laser-trimmed film resistors over both time and temperature are proposed. The structures are evaluated using computer simulations. This technique is substantiated with an example that shows an improvement in resolution of 4 bits when compared to that attainable with conventional bar resistors. 8 refs.

**090197 IMPROVED CIRCULAR DISK 3-DB HYBRIDS.** Methods of improvement on a planar-circuit-type 3-db hybrid consisting of a four-port circular disk-shaped resonator are proposed and described. Great improvement is obtained by rearrangement of the four ports upon consideration of the higher-order resonant modes and/or addition of a capacitive stub at the circumference of the resonator. Furthermore, the bandwidth of the hybrid is broadened considerably by adding an impedance step between the resonator and each 50- $\Omega$  coupling port. These improvements also are confirmed experimentally. (Edited author abstract) 9 refs.

**090198 RAREFICATION OF THE SPECTRUM OF A WAVEGUIDE-DIELECTRIC RESONATOR.** In a previous paper attention was drawn to the possibility of controlling the distribution of the spectrum of resonance frequencies of a waveguide-dielectric resonator by an appropriate choice of the critical frequencies (or dimensions) of the beyond-cutoff and resonant regions. However, there is no quantitative estimate available of the maximum achievable rarefaction of the resonance frequencies of the dominant and closest higher modes of oscillation of a waveguide dielectric resonator. In this article such an estimate is given for a rectangular waveguide-dielectric resonator. 3 refs.

Kapilevich, B.Yu. *Radioelectron Commun Syst* v 30 n 5 1987 p 99-101.

**090199 EFFECT OF LIQUID FAILURE ON ITS VIBRATIONS IN THE RESONATOR.** Formation of powerful hydroshocks in pipelines at excitation frequencies far from natural vibration frequencies of an ideal single fluid column is considered in terms of continuum mechanics. The algorithm for computing transient processes in a liquid is based on the Lax-Vedroff combined method with the flow correction. Data of numerical and experimental calculations are compared. The appearance of hydroshocks is accounted for by a rise in the gas content and drop in the natural vibration frequency of a fluid column up to the value equal to that of the excitation frequency. (Author abstract) In Russian. 18 refs.

**090200 ON THE STUDY OF MICROSTRIP RING AND VARACTOR-TUNED RING CIRCUITS.** Equivalent circuits have been derived for microstrip ring and varactor-tuned ring resonators. It was found that the resonant frequency is slightly lower as the coupling gap becomes smaller. The effects are small and generally negligible unless a very small coupling gap is used. Varactor-tuned ring resonators were developed with a tuning bandwidth of up to 15% of the operating frequency. The use of a dielectric covering layer reduced the insertion loss of the resonant ring to less than 1 dB. 24 refs.

**090204 ACCURATE ANALYSIS OF ARBITRARILY SHAPED PATCH RESONATORS ON THIN SUBSTRATES.** Based on a generalized edge boundary condition (GEB), an accurate analysis method for arbitrarily shaped microstrip patch resonators is developed. The edge of the patch and its feeding line are first discretized as a series of connected segments. Next, an equivalent voltage and an equivalent current are defined on each segment. This boundary of the patch and the feeding line can be viewed as an interface between two networks. The first takes into account the coupling under the patch. The second represents the dynamical edge effects and the coupling over the top side of the patch. This general and computer-efficient approach is then successfully applied to determine the input impedance of some commonly used probe-fed and strip-fed patch resonators. 21 refs.

## Cooling

**090207 COOLED DIELECTRIC RESONATORS FOR FREQUENCY STABILIZATION.** The characteristics of a new type of high-Q oscillatory system - cooled open dielectric resonators (DR) made of single-crystal leucosapphire - are studied theoretically and experimentally. A system of equations for the natural frequencies of the anisotropic dielectric resonator and the results of a numerical investigation of the system and an experimental evaluation of the accuracy are presented. The effect of the structural elements on the Q-factor of the resonator is examined. The behavior of the temperature coefficient of the resonance frequency  $\alpha_w$  of the leucosapphire DR in the temperature range 300-2 K is studied. The characteris-

tics of centimeter- and millimeter-band oscillators, which have been developed, based on the cooled leucosapphire DR are presented. (Edited author abstract). 20 Refs.

## Cylinders

**090208 RESONANT FREQUENCIES OF WHISPERING-GALLERY DIELECTRIC RESONATOR MODES.** Whispering-gallery dielectric resonator modes have shown their usefulness in millimeter wave integrated circuits. A method for the determination of the resonant frequencies of the whispering-gallery modes of cylindrical dielectric resonators is presented. Theoretical and experimental results are given. A comparison with other methods is made. (Edited author abstract) 8 refs.

Jiao, X.H. (CNRS, Limoges, Fr); Guillon, P.; Bermudez, L.A. *IEE Proc Part H* v 134 n 6 Dec 1987 p 497-501.

**Design** See Also ELECTROMAGNETIC WAVES—Scattering; GYROTRONS—Millimeter Waves.

**090209 WHISPERING-GALLERY MODES HERALD DR MM-WAVE USE.** At millimeter wavelengths, cylindrical dielectric resonators used in microwave integrated circuits become impractical. If conventional TE, TM, or hybrid modes are used, DRs will have dimensions that are impractically small. This article discusses how with only a slight configuration change, dielectric resonators (DRs) can be used as filters in the millimeter-wave range, with some unique electromagnetic radiation modes doing the work. 14 refs.

Guillon, P. (Univ de Limoges, Limoges, Fr); Jiao, X.H.; Auxemery, P.; Bermudez, L.A. *Microwaves RF* v 26 n 9 Sep 1987 8p between p 85 and 96.

**090210 PAVING THE WAY FOR STABILIZED DR OSCILLATORS.** The usefulness of dielectric resonators for frequency-stable oscillator circuits has been limited because the resonant frequency of the DR itself is not stable with variations in temperature. Moreover, the frequency change is not a straightforward function of the temperature change. This article presents an analytical approach which can simplify the modeling of dielectric-resonator temperature stability. 4 refs.

Jacques, Roger (CNET, Lannion, Fr). *Microwaves RF* v 26 n 9 Sep 1987 p 103-104, 106, 108.

**090211 SIMPLE EQUATIONS QUICKLY DESIGN CYLINDRICAL DRS.** Dielectric-resonator (DR) frequency, height, and radiation factors for TE<sub>018</sub> modes of operation have been difficult to calculate. Rigorous mathematical methods are computationally complex, making their use in practical applications almost prohibitive, and, the simpler, approximate methods are too inaccurate. However, the closed-form expressions derived are easy to use and more accurate than previous methods. 10 refs.

Mongia, Rajesh K. (Indian Inst of Technology, New Delhi, India); Bhat, Bharathi. *Microwaves RF* v 26 n 9 Sep 1987 5p between p 121 and 128.

**090212 COUPLING ANALYSIS MATCHES SPHERICAL DRS TO MICROSTRIP LINES.** Conventional, cylindrical dielectric resonators are difficult to use for millimeter wavelength applications because their dimensions are too small for easy manufacturing. Spherical dielectric resonators, however, are easier to produce at small dimensions. But, for these spherical resonators, predicting the coupling between the resonator and a microstrip transmission line has been traditionally difficult. This difficulty is eliminated with a coupling analysis and the resulting equations. 12 refs.

**090213 TWO-DIODE GUNN GENERATOR WITH A QUASIOPTICAL RESONATOR.** One of the most important problems in modern microwave electronics is to increase the power of semiconductor millimeter-band generators. This can be solved by using different constructions. However, the most widely used method is to add the powers of several diodes in a common resonator. In this case, it is possible to achieve acceptable summation, but at the price of reducing the frequency tuning range, which usually does not exceed a few percent. In this communication, we present the results of experimental investigations of the power and frequency characteristics of a two-diode Gunn generator with a quasioptical resonator. 9 refs.

Smorodin, V.V. *Radioelectron Commun Syst* v 30 n 5 1987 p 64-66.

**Dielectric Properties** See Also ELECTRIC FILTERS, BANDPASS—Design; OSCILLATORS, MICROWAVE—Stability.

**090214 COUPLING OF NON-AXIALLY-SYMMETRIC HYBRID MODES IN DIELECTRIC RESONATORS.** A method is developed for the rigorous calculation of the coupling coefficient between dielectric resonators excited in non-axially-symmetric hybrid modes. The technique is based on solving the boundary value problem for the fields and resonant frequencies in the combined two-resonator structures. A simplified circuit model representing the two coupled resonators is used to reduce the problem of coupling calculations to that of finding the resonant frequencies of two separate single resonators without solving the detailed boundary value problem. Experimental measurements of the coupling between the two lowest hybrid modes were performed to verify the models, and were found to be in excellent agreement with the calculations. 8 refs.

Zaki, Kawthar A. (Univ of Maryland, College Park, MD, USA); Chen, Chunming. *IEEE Trans Microwave Theory Tech* v MTT-35 n 12 Dec 1987, 1987 MTT-S Int Microwave Symp, Las Vegas, NV, USA, Jun 9-11 1987 p 1136-1142.

**090215 PROPERTIES OF SHIELDED CYLINDRICAL QUASI-TE<sub>0mn</sub>-MODE DIELECTRIC RESONATORS.** Comparison of the Rayleigh-Ritz method and the mode-matching method for computations of quasi-TE<sub>0mn</sub>-mode frequencies and unloaded Q factors of shielded dielectric resonators is presented. Rigorous bounds for the true quasi-TE<sub>0mn</sub>-mode frequencies are assessed. Influence of various parameters on the resonant frequencies, unloaded Q factors, and the temperature coefficients of the resonant frequency is demonstrated for many shielded dielectric resonator structures. Different approaches to unloaded-Q-factor computations are discussed and numerically compared. 12 refs.

## Evaluation

**090217 ELECTRIC FIELDS AND LOSSES IN LUMPED ELEMENT RESONATORS FOR ESR SPECTROSCOPY.** This paper presents closed expressions for the electric field in lumped element resonators

used for ESR spectroscopy and an evaluation of the frequency dependence of the dielectric losses. The dielectric losses depend on the type of resonator used and the results show that multi-gap resonators are very effective in reducing their effect. The comparison between magnetic and electric losses indicates that, for properly designed resonators and sample diameters of the order of 15-20 mm, the magnetic losses will predominate. (Author abstract) 15 refs.

Sotgiu, A. (Univ dell'Aquila, L'Aquila, Italy); Momo, F.; Gualtieri, G.; Adriani, O. *J Phys E* v 20 n 12 Dec 1987 p 1487-1490.

## Fabrication

**090218 MICROWAVE BULK-ACOUSTIC-WAVE REFLECTION-GRATING RESONATORS.** A technique for fabrication of bulk-acoustic-wave (BAW) resonators operating at fundamental frequencies between 1 and 10 GHz is presented. The resonators utilize a reflection grating made by optical holographic methods in iron-doped lithium niobate. Q factors of 30000 at 1 GHz have been demonstrated. Extension to Q of 10000 at 10 GHz appears feasible. Projected limitations to performance are discussed. The high Q at the high fundamental frequency directly results in low-phase noise. Phase-noise measurements of BAW resonator-stabilized oscillators operating at 1.14 GHz are presented. The single-sideband noise floor of  $<-140$  dBc/Hz is shown to be in agreement with an analytical model. Projected improvements in the devices and circuits promise performance of  $<-160$  dBc/Hz. 23 refs.

Oates, Daniel E. (MIT, Lexington, MA, USA); Pan, Jeffrey Y. *IEEE Trans Ultrason Ferroelectr Freq Control* v 35 n 3 Feb 1988, 34th Nucl Sci Symp, San Francisco, CA, USA, Oct 21-23 1987 p 315-322.

**090219 SAW RESONATOR DESIGN AND FABRICATION FOR 2.0, 2.6 AND 3.3 GHz.** Direct-write electron-beam lithography has been used to fabricate surface-acoustic-wave (SAW) resonators in quartz at 2.05, 2.60, and 3.30 GHz. Typical 2.05 GHz devices show unloaded Q factors of about 2700 and insertion losses of about 9 dB. The best 2.60 GHz devices have unloaded Q of about 2000 with insertion losses less than 11 dB. Preliminary 3.3 GHz devices have shown unloaded Q of about 1600 and insertion losses of 17 dB. These results are for devices tested in chip form in a 50- $\Omega$  system. The fabrication of a fundamental-mode resonator with center frequency exceeding 2.6 GHz is claimed to be unmatched in the literature. These results are due in part to improvements in design and electron-beam direct-write capabilities. Design and fabrication of SAW resonators above 2 GHz are described, test results for several wafers including preliminary phase noise measurements for devices at 2 GHz are reported, and problems associated with testing these devices are discussed. 13 refs.

Pendergrass, Larry L. (Hewlett-Packard Co, Santa Rosa, CA, USA); Studebaker, Lawrence. *IEEE Trans Ultrason Ferroelectr Freq Control* v 35 n 3 Feb 1988, 34th Nucl Sci Symp, San Francisco, CA, USA, Oct 21-23 1987 p 372-379.

## Ferrite

**090220 NOUVELLE METHODE DE DETERMINATION DES PARTIES REELLES DES PARAMETRES ELECTRIQUES ET MAGNETIQUES DES RESONATEURS A FERRITES SATURES ET NON SATURES.** [New Method of Determination of Real Parts of Dielectric and Magnetic Parameters of Saturated and Nonsaturated Ferrite Resonators.]. Real parts of dielectric and magnetic material parameters of saturated and partially magnetized ferrites are determined in the frequency range: 2.5-4 GHz. Formulas of the tensor permeability elements are not used for the calculation of these parameters which are deduced from the degenerated resonant frequencies of the  $TM_{020}$  and  $TM_{-210}$  modes. These frequencies are measured in an appropriate metallic cavity containing a ferrite disk suitable for a 2 GHz circular. (Edited author abstract). 14 Refs. In French.

## Ferrite Applications

**090221 THREE-PORT FERRITE RESONATOR CIRCUIT USING COPLANAR WAVEGUIDE.** A three-port magnetically-tunable ferrite resonator circuits proposed, which uses a ferrite resonator and coplanar waveguide on a dielectric substrate. This circuit has both resonator and isolator properties, and is applicable to a magnetically-tunable oscillator using with an active component. It is not necessary to use an additional isolator for reducing the influence of the reflected power on the oscillation. Experiments are done with YIG and CaVG ferrite. The existence of an optimum position for placing ferrite to obtaining the maximum non-reciprocity, is ascertained by the theoretical and experimental results. This circuit is simple in construction, and suitable for wide-band operation. 6 refs.

## Impedance Matching

**090222 IMPEDANCE MATCHING AND STABILIZATION OF RF RESONATORS.** The study of nuclei possessing high angular momenta demands beams of heavy ions with an energy sufficient to overcome the Coulomb barrier for relevant combinations of projectile and target. This demand has motivated the design and construction of a postaccelerator for the 9 MV tandem Van de Graaff at the Niels Bohr Institute. In connection with the postaccelerator system presently being installed at the NBI tandem, general considerations and formulae for resonator matching and stabilization are presented. 9 refs.

**090223 STATISTICAL MODEL OF AN ADAPTIVE TWO-MIRROR UNSTABLE RESONATOR.** The cancellation of phase fluctuations of a wave field in an open unstable resonator is discussed. Cancellation effectiveness is investigated both within the resonator and at its output. Cancellation outside the resonator is shown to be more effective for phase variations of higher dynamic range. Features of an adaptive resonator compared with adaptation without an optical resonator system are pointed out. (Author abstract) 7 refs.

**090224 EINE ASYMPTOTISCHE METHODE ZUR BERECHNUNG NICHTLINEARER HELMHOLTZRESONATOREN.** [Asymptotic Method for Calculating Nonlinear Helmholtz Resonators.]. The acoustic nonlinearity of a Helmholtz resonator is caused by the fact that the flow resistance of the orifice increases with increasing particle velocity amplitude. By extending the asymptotic method of Krylov, Bogoljubov and Mitropolski we calculate the nonlinear oscillations in the tube-resonator-system, the amplitudes of the higher harmonics, the resonance curves and the decay of the amplitudes caused by the nonlinear dissipation. In addition the method enables us to include further nonlinear or dissipative effects, to treat other forms of external excitation or to consider tubes with Helmholtz resonators coupled at both ends. In all cases the numerical evaluation

only takes a very short time. (Edited author abstract) In German. 21 refs.

**090225 HIERARCHY OF TERMS IN A MULTI-POLE EXPANSION.** In the classical multipole expansion the various terms (dipoles, quadrupoles etc.) are ranked according to powers of the wavenumber k. When  $k \rightarrow 0$  the dominant terms are those of lowest powers, provided the moments are k-independent. However, this situation does not always hold, and the hierarchy may be upset when the current structure markedly changes with k. The point is illustrated by the example of the confined modes of a dielectric resonator. (Author abstract) 2 refs.

**090226 ANALYSE DER ANKOPPLUNG DIELEKTRISCHER RESONATOREN AN MIKROSTRIP-LEITUNGEN.** [Analysis of Dielectric Resonators Coupled to Microstrip Lines.]. This paper presents an analysis of cylindrical dielectric resonators coupled to one and two microstrip lines. The coupling parameters and the elements of the electric equivalent networks are calculated. The effects of the change of parameters are investigated. The dielectric resonator coupled to two microstrip lines acts as a bandpass filter. This structure is analysed with open- and short-circuited as well as match-terminated transmission lines. Methods for the measurement of unloaded and loaded quality factors are discussed. Measured data of a 6-GHz dielectric resonator in bandstop filter configuration are presented. (Author abstract) 17 refs. In German.

**090227 APPROXIMATE RELATIONS FOR CALCULATING THE RESONANCE FREQUENCY OF  $H_{018}$  MODES OF OSCILLATION OF CYLINDRICAL DIELECTRIC MICROWAVE RESONATORS.** The solution of boundary value problems on the  $H_{018}$  modes of circular cylindrical dielectric microwave resonator in free space and with plane and metal screens reduces to a complex form of characteristic equations. It is possible to solve them by numerical methods using high-speed computers having effective algorithms for calculating cylindrical Bessel functions of the first kind and MacDonald functions of different orders as part of their software, but this involves a considerable amount of computer time. The calculations can be simplified considerably and carried out using a microcomputer or microcalculators if one uses simple approximate relations, which are obtained in the present paper by making use of the particular features of the solutions of the characteristic equations. 6 refs.

Chernii, B.S. *Radioelectron Commun Syst* v 30 n 5 1987 p 92-95.

**090228 IMPROVING EXCITATION EFFICIENCY OF DISK DIELECTRIC RESONATORS.** In most self-excited microwave oscillator circuits that use disk dielectric resonators (DDR) to stabilize the frequency, the resonators are excited by the radiating aperture of a metallic waveguide. For a specified level of the DDR loaded Q,  $Q_1$  waveguide coupling devices (exciters) make it possible to obtain stronger coupling with a DDR than coaxial, microstrip, or other devices. Owing to diffraction losses of energy in excitation of the DDR a decrease in the distance between the radiating aperture and the resonator surface is accompanied by a drop in the loaded Q of the DDR that is more rapid than the increase in the coupling coefficient  $\beta_{cp}$ . The problem of improving the efficiency of

existing waveguide exciters therefore remains acute. We show that by going from single to multielement coupling devices it is possible to realize more fully the advantage of a DDR in terms of  $Q$  when compared with other kinds of resonators. Selective excitation of oscillations at the required DDR modes is ensured. 2 Refs.

**090229 EXPERIMENTAL CHARACTERIZATION OF MULTIMODED MICROWAVE RESONATORS USING AUTOMATED NETWORK ANALYZER.** A computer-assisted procedure for accurate determination of microwave-resonator lumped-element equivalent circuit parameters is described. The technique is based on vector network analyzer measurements, and is applicable to multiple resonant modes in close frequency proximity as well as isolated single resonances. Data from either reflection or reaction type measurements may be numerically processed by the same procedure. Results are presented and discussed for several shielded dielectric resonator cases of practical interest. 12 refs.

**090230 TUNABLE MICROWAVE RESONATORS AND OSCILLATORS USING MAGNETOSTATIC WAVES.** The status of magnetostatic wave (MSW) straight-edge resonators (SERs) and their applications in tunable oscillator circuits are reviewed. The resonators are based on magnetostatic waves propagating in high- $Q$  cavities fabricated in thin ferrimagnetic yttrium iron garnet (YIG) films. The resonance frequency of these resonators can be tuned using a bias magnetic field. The theory of operation and design criteria for the straight-edge resonators are described with emphasis on the effect of the resonator parameters on the tuning range, power handling, and phase noise performance. The use of the SER as the frequency-selective element in oscillator circuits is reported. Examples of tunable oscillators are included. 31 refs.

**Oscillations** See Also GYROTRONS—Analysis; WAVEGUIDES, OPTICAL—Oscillations.

**090234 INTERACTION EFFECTS OF AZIMUTHAL OSCILLATIONS IN DIELECTRIC DISK RESONATORS.** In order to achieve high and ultrahigh  $Q$  levels in the microwave and EHF wave bands it is advisable to use open dielectric resonators with azimuthal oscillations (DRAO) in the form of dielectric disks. In order to eliminate the deleterious consequences of the interaction effects several measures are necessary: the implementation of measures for controlling the oscillation spectrum of the DRAO; a discrimination of nonoperating oscillations; an optimization of the construction of the coupling devices; and the elimination of harmful defects in the shape of the dielectric resonators. 6 refs.

**Performance** See Also ELECTRODES—Performance.

**090235 BETTER COUPLING MODEL OF DR TO MICROSTRIP ENSURES REPEATABILITY.** The lack of simple, accurate models for determining performance dielectric resonators (DRs) coupled to microstrip lines makes repeatable design of DR filters and oscillators extremely difficult. An examination of some DR coupling models will clarify why one model is a more accurate method of predicting unloaded  $Q$  of the DR. This model includes resistive losses and loaded  $Q$ , and is valid with or without the use of dielectric spacers between the DR and the substrate. 10 refs.

## Spectrum analysis

**090238 FREE OSCILLATIONS IN A COAXIAL-WAVEGUIDE RESONATOR.** The problem of determining the spectrum of free oscillations in a coaxial-waveguide resonator (CWR) is discussed in a rigorous

formulation. A uniqueness theorem is proved. A rigorous mathematical model describing the spectrum of natural axially symmetric oscillations in the resonator is constructed and the corresponding calculation algorithm is proved and realized. The natural oscillations in a CWR are analyzed in detail and classified. A relationship between the excitation of natural oscillations and the scattered characteristics is established. (Author abstract) 9 refs.

## Stability

**090239 THERMAL STABILITY OF PHASE-CONJUGATE RESONATOR.** The condition for thermal stability of the phase-conjugate resonator (PCR) is derived by means of the transfer matrix method. It is pointed out that the PCR is not certainly thermo-stable if only the condition  $G_1 G_2^{-1/2}$  is satisfied. Therefore, optimal design of the PCR is necessary in order to obtain high-quality output beams. The localization phenomenon of compensating distortions by using phase-conjugate techniques can be explained with the results obtained in this paper. (Author abstract) 6 refs. In Chinese.

**090241 BISTABLE PROPERTIES OF A NONLINEAR FABRY-PEROT RESONATOR WITH ACOUSTOOPTICAL INTERACTION.** The effect of acoustooptical (AO) interaction on the bistable properties of a Fabry-Perot (FP) resonator into which a nonlinear medium is inserted, is studied theoretically. It is shown in the Bragg diffraction approximation that for low diffraction efficiency over the length of the resonator AO interaction leads primarily to modulation of phase detuning from exact resonance of the FP resonator. In this case AO interaction may either only transfer the system from one stable state to another in the vicinity of the threshold fields for onset of bistability or, if the AO interaction in the resonator is efficient, it can lead to strong modulation of the radiation passing through and reflected from the resonator, when over one period of the sound the dependence of the amplitude of the transmitted signal on the amplitude of the input signal encompasses the entire hysteresis loop. (Edited author abstract). 4 Refs.

## Temperature Measurement

**090242 INVESTIGATION OF TEMPERATURE CHARACTERISTICS OF SINGLE CRYSTAL SAPPHIRE DISK DIELECTRIC RESONATORS.** To define the value of  $\alpha_\omega$  more accurately, single crystal sapphire disk resonators were studied in the temperature range between 2°K and 300°K. The measurements were performed in the 8-10 GHz band. Disk DRs (Dielectric Resonators) were made of single crystal sapphire grown using the State Optical Institute method. The types of the induced oscillations, geometrical dimensions  $D$  and  $L$ , and the disk geometric axis deviation from the crystal's optical axis  $\Delta\phi$  for the studied resonators are given. The

Q-factor of the DR was measured using the dynamic method and recording the resonant curve on a two-coordinate plotter, which also allowed us to control the structure and the shape of the resonant curve. An analysis of the experimental data indicates that in the region of liquid-helium temperature, the  $\alpha_{\omega}(T)$  behavior of the single crystal sapphire disk resonators has an anomalous character, which is determined by the impurities in the crystal. Stabilizing the DR temperature in the region where  $\alpha_{\omega}(T) \approx 0$  will allow one to increase substantially the stability and the reproducibility of the natural resonant frequency of the DRs, which are used for frequency stabilization. 9 refs.

## Testing

**090243 FREQUENCY CHARACTERISTIC OF A WAVEGUIDE WITH A DIELECTRIC RESONATOR.** When a dielectric resonator is connected to a waveguide, in addition to intense resonance perturbation of the microwave field at frequencies close to the resonance frequency for all modes of oscillation of the dielectric resonator, there is also a comparatively weak perturbation of the field, which, in the frequency band employed, does not have a resonance form. This nonresonant background is due to large values of the volume of the dielectric resonator and the permittivity of the materials employed. This paper takes into account the nonresonant perturbation, which leads to asymmetry of the amplitude-frequency characteristics of structures with dielectric resonators, in order to increase the accuracy of these characteristics. 6 refs.

## Thin Films

**090245 THIN-FILM BULK-ACOUSTIC-WAVE RESONATOR-CONTROLLED OSCILLATOR ON SILICON.** A composite ZnO bulk-acoustic-wave thin-film resonator (TFR) has been fabricated on a silicon substrate with a double-diffused bipolar junction transistor (BJT). Fabrication techniques unique to the integration of the TFR are discussed. The integrated TFR-BJT structure was configured as a VHF Pierce oscillator circuit with a fundamental frequency of 257 MHz. Phase noise is better than  $-90$  dBc/Hz at a 1-kHz offset. Temperature stability is  $-8.5$  ppm/°C from 5°C to 65°C and  $-3.75$  ppm/°C from  $-55$ °C to 5°C. The integration of the TFR with active components is viewed as a development toward large-scale RF circuit integration. 8 refs.

**090247 NUMERICAL CALCULATION OF THE NATURAL FREQUENCIES OF A RESONATOR WITH A DIELECTRIC LAYER HAVING AN ARBITRARY PERMITTIVITY PROFILE.** A numerical method is proposed for calculating the natural frequencies of a resonator containing a dielectric layer with an arbitrary permittivity profile. A dispersion equation for the resonance frequencies is obtained, special features of the algorithm are discussed, and results of the analysis of some specific types of resonators are presented. (Author abstract) 6 refs.

Kapilevich, B.Yu. *Sov J Commun Technol Electron* v 32 n 4 Apr 1987 p 8-12.

**090248 MICROPHONIC SENSITIVITY OF SURFACE-ACOUSTIC-WAVE RESONATORS.** The shift in resonant frequency due to acceleration has been measured for surface-acoustic-wave resonators (SAWRs). SAWR devices were subjected to vibration from 5 Hz to 10 kHz with peak accelerations ranging from  $10^{-2}$  to  $10^3$  g. The vibration was applied both normal to and in the plane of propagating surface wave yielding microphonic sensitivities on the order of 1 ppb/g. To confirm the results of the direct measurement method, an oscillator loop was closed around the vibrated SAWR and the magnitudes of the FM sidebands were measured to indicate the resulting frequency shift. Several bulk crystal resonators were also measured and it was found that the microphonic sensitivities were generally comparable in magnitude to those of the SAWRs but spanned much wider ranges. 14 refs.

**090251 EFFECTS ON THE RESONANT FREQUENCIES CAUSED BY LOADING A SPHERICAL CAVITY WITH A DIELECTRIC SPHERE.** An extensive investigation has been carried out of the properties of a conducting spherical cavity filled with a lossless homogeneous dielectric and concentrically loaded with another lossless homogeneous dielectric. This report contains a portion of the results obtained in the course of this investigation. Also presented and discussed are the effects on the cavity system eigenvalues of changing the radius of the dielectric load sphere. This is done for a wide range of relative dielectric strength for the media within the cavity. Specifically, results for relative strengths of 3, 10, and 1/3 are given. The appropriate derivations of the eigenvalue equations are presented. Analysis of the results suggests a broad variety of practical applications. (Edited author abstract) 5 refs.

**090253 VOLTAGE FREQUENCY CONTROL OF A SUPERCONDUCTING CAVITY STABILIZED OSCILLATOR.** A simple electrical tuning method for a superconducting cavity is described. Tuning is achieved by a reflection-type varactor phase shifter coupled loosely by a directional coupler to the transmission line which conducts the RF power to the cavity. The tuning section is outside of the cryogenic environment, and the tuning characteristics can be adjusted simply by changing the coupling coefficient of the coupler. The general characteristics of the method are discussed. The tuning properties of a superconducting cavity stabilized oscillator (SCSO), using a superconducting cavity as a frequency discriminator, are then calculated. The calculations are confirmed by preliminary experiments using a manual phase shifter in the 9.2-GHz SCSO. Tuning ranges similar to commercial precision quartz crystal oscillators can be easily obtained. 12 refs.

## Calculations

**090257 Q FACTOR OF A CYLINDRICAL CAVITY WITH A COAXIAL PROTRUSION.** A rigorous method for carrying out an electrodynamic calculation of the characteristic  $E_{0np}$  oscillations of a cylindrical cavity with a coaxial protrusion, taking into account the finite conductivity of the walls, is examined. The analysis is performed by the modified method of residues, extended here to the problem of characteristic oscillations. Approximate analytic relations are obtained for the Q factor and the results of numerical calculations for  $E_{010}$  oscillations are presented. They are compared with measurements and it is shown that they agree well with the theoretical results and with experiment. (Author abstract) 17 refs.

**090258 IMPLEMENTATION OF A RESONANT CAVITY PACKAGE ON MIMD COMPUTERS.** The task of calculating the lowest few eigenvalues of Maxwell's equations for a resonant cavity of moderately complicated shape easily exhausts the capacity of present-day computers. Massively parallel MIMD-systems would provide the necessary memory size and computing power, but the problems of implementing the algorithms are not solved yet. The present paper studies some ways of partitioning the computation for an existing software package and evaluates the resulting requirements for memory size, communication capabilities and computing power. It turns out that for realistic communication networks the minimal size of a subtask that can efficiently be treated by one processor is quite large, thus placing a limit to the reasonable amount of parallelism for a given problem size. (Author abstract) 11 refs.

## Cylinders

**090259 UNIFIED APPROACH TO DETERMINATION OF MODES IN CYLINDRICAL CAVITIES AXISYMMETRICALLY LOADED WITH DIELECTRICS.** Based on a variational expression, a unified approach for the determination of all modes in cylindrical cavities axisymmetrically loaded with dielectrics is presented. This approach employs one-dimensional finite-element basis functions along the r-axis, and uses a penalty term to alleviate the resulting spurious modes. Using this technique, the resonant frequencies of several cavities are calculated. (Author abstract) 8 refs.

## Materials

**090262 POSSIBLE HIGH-FREQUENCY CAVITY AND WAVEGUIDE APPLICATIONS OF HIGH TEMPERATURE SUPERCONDUCTORS.** The authors discuss possible implications of high temperature superconductors for cavity and waveguide operation and describe possible applications. Based on experimental evidence a variety of microwave/far infrared resonator and waveguide components might be developed with high temperature superconductivity materials. These relatively small scale applications do not require thick materials, electrical contacts, special materials interfacing as in semiconductor devices, or special structural support. However, there are a number of obstacles that may inhibit their development. The RF surface resistance can be severely affected by boundaries, random grain alignment, and the presence of nonsuperconducting material.

**Microwaves** See Also CLOCKS, ATOMIC—Mathematical Models; ELECTRIC CABLES—Nondestructive Examination; WAVEGUIDE COMPONENTS—Couplers.

**090265 INVESTIGATION OF HEMISPHERICAL RESONATOR FOR AN ENERGY STORE.** High-power microwave pulses can be generated by the slow storage of energy in a resonant cavity, and the subsequent discharge of this energy in a time interval much less than the storage time. The amplitude of the radio pulse obtained depends on the volume of the cavity, its Q, the stored energy density, and the nature of the operation of the switching device. The simplest method of increasing the level of stored energy in the resonant system is to increase its volume while simultaneously choosing the optimum geometry. We give some results of an investigation of a superdimensional hemispherical copper resonator for the purpose of using it as an energy store when generating microwave pulses. 6 refs.

## Millimeter Waves

**090268 PLANAR OROTRON EXPERIMENTS IN THE MILLIMETER-WAVELENGTH BAND.** The planar orotron is introduced and shown to be a viable source of moderate power and of millimeter and submillimeter wavelength radiation. The resonator is a slow-wave structure consisting of a rectangular metal grating which is opposed by a planar conducting boundary. The device operates in the surface harmonic mode: electrons interact with axially traveling waves which evanesce above the grating surface, and the amplified radiation leaves the resonator in parallel with the beam axis. Operation in both the forward and the backward mode is possible. The resonator cavity is designed to enhance longitudinal reflections, and thereby enhance the output power and efficiency. The output frequency and tuning range are determined by the grating parameters. Experiments performed in the backward mode have produced radiation from 30 to 110 GHz at power levels ranging from 100 W to 2 kW. The efficiencies vary from 1 to 7%. The measured frequencies are closely predicted by a theory which is also presented. 10 refs.

## Mathematical Models

**090280 ANALYSIS OF TRAPPED ENERGY RESONATORS WITH TABS.** A theoretical model is presented for analyzing the effects of tab electrodes on trapped energy resonators with rectangular electrodes. A tab of a strip type extending along the Z' axis on an AT-cut rectangular plate is treated. The model is based on the mode-matching method so that it can accurately describe two-dimensional displacement fields. Equations that determine the resonant frequencies, mode shapes, and mode strength are derived. The calculated results of resonant frequencies and inductances for AT-cut third overtone resonators are compared with measured results. It is shown from the comparison between experiment and theory that the model predicts well the strong acoustical effects of tabs on anharmonic trapped modes having phase reversals in the tab direction and little effect on the main and other anharmonic spurious modes. 8 refs.

**090282 FOUR-FREQUENCY PROCESS FOR COUPLED-DUALS USING ERROR-CORRECTED S-PARAMETER MEASUREMENTS.** Although the four-frequency measurement process has been used successfully on coupled dual crystals from 9.4 MHz to 21.4 MHz, discrepancies between the crystal data and filter data at 45 MHz and 57.5 MHz suggested an error problem associated with the measurement system. To eliminate the errors, a twelve-term error model was chosen and the equations were derived for use with an automatic network analyzer. The details of the direct deviation of the four-frequency measurement process are given in which the two resonator frequencies and the synchronous peak separation frequency (SPSF) of a coupled dual crystal are calculated from the two frequencies of the zeros of the short-circuit driving point impedance, and the two frequencies of the zeros of the open-circuit driving point impedance. Determination of the four frequencies from the error-corrected S parameters is discussed, as well as the analysis of an external capacitor placed across the output circuit to obtain a more convenient distribution of the four frequencies. A comparison is made between data taken on the original fixture and data taken on an automatic network analyzer using error-corrected S parameters. 10 refs.

## Measurements

**090283 X-RAY BRILLOUIN SCATTERING OF MOESSBAUER RADIATION BY AN OSCILLATING QUARTZ CRYSTAL.** The elastic and inelastic scattering from x-cut quartz single crystal is investigated by means of Mossbauer diffractometry from the (112-0) Bragg plane using a  $^{57}\text{Co}$ -source and a Mossbauer absorber for the energy analysis. When the crystals is excited to piezo-electric vibrations in the MHz-range, inelastically scattered quanta are resolved. The phonon energies are in the range  $40\text{ neV} < h\Omega_q < 150\text{ neV}$ . (Author abstract) 15 refs.

**Quartz Applications** See Also OSCILLATORS, CRYSTAL—Quartz Applications.

**090285 SUPPRESSION OF ANHARMONIC SPURIOUS MODES IN QUARTZ RESONATORS BY MODIFIED ELECTRODE DESIGN USING CHARGE CANCELLATION.** One important problem in the design of the thickness vibration resonator is how to suppress the anharmonic higher-order spurious mode which is generated near the main resonant frequency. It is easy to realize a single resonant characteristic by the design based on the trapped energy theory, but the area of the electrode and, consequently, the inductance, are limited. This paper proposes a method which improves this point and increases the degrees of freedom in the design, suppressing the anharmonic spurious mode by

adding a mass to the edge of the electrode and by cancelling the charge. A modified circular electrode structure is proposed in which the peripheral part (ring) of the electrode has a larger thickness. The third overtone resonator is analyzed, and it is shown theoretically that the dominant (3, 3, 1) spurious mode is suppressed by the charge cancellation, thereby realizing a resonator with an essentially single resonant characteristic over a wide frequency range. The charge cancellation characteristics for the spurious mode are strongly dependent on the platebacking of the ring electrode. The data for the optimum design are summarized in a table. (Edited author abstract) 5 refs.

Sekimoto, Hitoshi (Tokyo Metropolitan Univ, Tokyo, Jpn); Ihara, Toshiyuki; Nakata, Hozumi; Miura, Masaaki. *Electron Commun Jpn Part 1* v 71 n 4 Apr 1988 p 26-33.

**090286 STATE OF THE ART OF FLICKER FREQUENCY NOISE IN BAW AND SAW QUARTZ RESONATORS.** Experimental results of the last 15 years are reviewed. Noise properties of crystal filters and oscillators are reported, along with practical measurements. It is shown that the additional phase fluctuations are compensated by frequency fluctuations and vice versa. With the assistance of these theoretical results the flicker and white frequency noise coefficients,  $h_{-1}$  and  $h_0$ , respectively, are plotted versus unloaded Q and carrier frequency  $f_0$  for the measured and published crystal oscillator noise characteristics. The dependence of  $h_{-1} \approx 10^{-12.75} Q^2$  is verified. 63 refs.

## Radiation Effects

**090287 LOW- AND MEDIUM-DOSE RADIATION SENSITIVITY OF QUARTZ CRYSTAL RESONATORS WITH DIFFERENT ALUMINUM IMPURITY CONTENT.** The results of low (4.0-radiation) and medium (1000 rad)-radiation tests on AT quartz crystal resonators with aluminum impurity content of 0.79 and 8.3 PPM are discussed. The radiation tests were conducted with two  $^{60}\text{Co}$  sources that generate photons with a mean energy of 1.25 MeV. The dose rate at the quartz crystal blanks was approximately 4.0 rad(Si)/h, which represents approximately ten times the dose rate experienced in the radiation environment of a low earth orbit. A mathematical analysis of the frequency susceptibility versus total accumulated dose revealed that a least-squares fit of the  $df/f$  versus accumulated dose R data is of the type  $df/f(R) = AR^B$  where A and B are real rational coefficients. Interpretation of this result is presented, together with data on the Allan variances and aging rates of the oscillators during and after the radiation tests. 14 refs.

## Thermal Effects

**090288 TEMPERATURE HYSTERESIS OF FREQUENCY IN QUARTZ RESONATORS.** The causes of temperature hysteresis in quartz resonators have not as yet been fully explained. In what follows, an explanation is offered for the frequency-change effect that reveals the mechanism of phenomena occurring during a temperature change in a resonator under various conditions. A quantitative evaluation is made of the factors that determine the resulting frequency change. 8 refs.

Tartakovskii, I.I. *Meas Tech* v 30 n 6 Jun 1987 p 563-566.

## RETAINING WALLS

**090289 EARTH-ANCHORED WALL AIDS RECONSTRUCTION WORK.** The New York Department of Transportation encountered a problem in its \$150-million program to improve vehicular traffic flow on the Long Island Expressway. For a stretch of 1650 feet, insufficient embankment width existed to construct a traditional retaining wall for a two-lane, collector-distributor roadway. To solve this problem, design engineers Berger, Lehman Associates, and the DOT came up with the solution of a permanent earth-anchored wall. The design generally uses steel H-piles on 8-ft. centers. Timber lagging is installed as excavation progresses. As the tie location points are reached, holes are drilled for them, usually at a 15-degree angle with the horizontal - except where existing utilities or foundations dictate greater slopes - and anchors are placed, grouted, stressed, and tested. Excavation is continued and the process repeated until final subgrade is reached.

Anon. *Better Roads* v 57 n 10 Oct 1987 p 48.

**090290 STUDIES ON THE JOINT STRUCTURE BETWEEN FOOTING CONCRETE AND STEEL SHEET PIPE PILE WALL.** Several joints between footing concrete and steel sheet pile wall have been used, but their shear transfer mechanisms of the joint have not been made clear fully under present conditions. Therefore small scale and large scale model tests with some different joints including a new proposed joint are carried out, and their shear transfer mechanism has been investigated based on tests. Consequently, the proposed joint structure which has sufficient shear transfer capability and construction efficiency has been applied successfully at Katsushika Edogawa line, Metropolitan expressway in Japan. (Author abstract) In Japanese. 16 refs.

## Analysis

**090292 STATIC ANALYSIS MODEL FOR DOUBLE SHEET-PILE WALL STRUCTURES.** A calculation model for estimating static behavior when a double sheet-pile wall structure is subjected to horizontal force is proposed, and a comparison is made between the results of calculations and those of model tests to examine the validity of the calculation model. The calculation model is based on the theoretical solution obtained by assuming that the portion of the structure above ground level is a composite of sheet piles and sand fill and that the portion below ground level consists of sheet piles receiving horizontal resistance from the ground, taking into consideration the elasto-plastic characteristics of the sand fill and the subsurface soils. (Edited author abstract) 13 refs.

**Concrete Construction** See Also SHORE PROTECTION.

**090294 CANTILEVERED CONTIGUOUS PILED RETAINING WALL.** The project involved the construction of a concrete retaining wall (which will eventually be given a brick cladding to conform with the appearance of the superstore), some 13m high, adjacent to a number of buildings situated on the rear boundary of what will be the superstore's car park for shoppers' vehicles. The wall was designed as a contiguous piled structure, on top of which has been provided a reinforced concrete waling beam, followed by installation of temporary ground anchors to tie the wall back, stressed to give support to the top of the piles. Excavation was then undertaken to expose the 97 piles which, acting as 750mm-diameter vertical beams, had been augered to depths of between 5 and 12m.

Barfoot, Jack. *Concrete (London)* v 21 n 10 Oct 1987 p 13-14.

**090295 HEAVILY-ANCHORED RETAINING WALLS ON OKEHAMPTON BY-PASS.** There are three principal retaining walls designated as south, north and inter-carriageway. The south wall is on the high side of the cutting, and is quite critical because of its effect on the haul road on what is a site with limited access. This south wall has also posed certain problems in its construction, for example, in its variance of height and in the need to cast its in situ panels in single pours. The method of construction is explained including the use of a light shutter to construct the panels in single pours.

Barfoot, Jack. *Concrete (London)* v 22 n 2 Feb 1988 p 24-26.

**090296 NEWBIGGIN SEA DEFENCE WILL BRING LOCAL 'PEACE OF MIND'.** At an early stage in conception, the consulting engineers undertook a survey of Newbiggin Bay's patterns of wind, waves and tides, using a mathematical model to hypothesise the worst storm conditions likely in the next 50 years. Based on this, they assessed the environmental and economic options, and subsequently tested a scale model in a hydraulic tank. The project is 400m in length, sited on the foreshore and covering the worst-affected area, which is the center of Newbiggin at Bridge Street. It consists of a series of precast and in-situ reinforced-concrete beams on imported filling, in front of a new curved deflector wave wall situated generally seaward of the old sea wall, part of which has suffered severe storm damage in the past.

Barfoot, Jack. *Concrete (London)* v 22 n 6 Jun 1988 p 15-16, 18-19.

**Construction** See Also PILES—Concrete; SUBWAYS—Stations.

**090297 HOLDING BACK THE EARTH.** Precast concrete for retaining walls has several strong advantages over cast-in-place techniques. The quality of precast concrete is generally higher and the control over quality is much better due to the ability to tightly control casting conditions. Another advantage of precast systems is the rapidity of construction - especially on-site construction. The precast systems vary, but a typical installation rate is about 1000 ft<sup>2</sup> (019 m<sup>2</sup>) per shift using only a five-man crew. That, of course, does not account for labor to produce the precast members, but still results in a significant price advantage. There are several distinct types of precast retaining walls. Reinforcing the backfill to create a self-supporting block of soil is one method that has gained increasing popularity around the world. Other retaining wall systems that are now on the market are essentially modern equivalents of that most ancient of all

retaining walls: the gravity wall. 10 refs.

**090298 CONFORTATION PROVOISIRE D'UN TALUS DE DEBLAI PAR CLOUAGE.** [Provisional Consolidation of a Cutting Slope by Nailing]. This article describes a case of the provisional repair of a chalk debris slope in an urban site by means of nailing. This remedial work was undertaken following an earth slide which occurred during the building of a reinforced concrete retaining structure at the bottom of an urbanized slope. After an earth abutment had been sent in place at the toe, nailing made it possible to stabilize the slope in a very short time and to build the retaining structure initially planned. The article describes the design of the nailing, the techniques employed, and their adaptation to the difficulties encountered. (Author abstract) In French.

## Failure

**090299 COLLAPSE OF DIAPHRAGM WALLS RETAINING CLAY.** Five centrifugal model tests are reported which illustrate aspects of the collapse of stiff cantilever retaining walls embedded in overconsolidated clay. The drainage of a heavy fluid in flight was used to simulate the effects of excavation, following the establishment of a high initial groundwater level. Two modes of collapse were observed with unproped walls. The temporary stability of walls with small penetration was interrupted by the hydraulic action of a water-filled crack opening on the retained side of the wall. The long-term rotational failure of walls of deeper penetration was also observed, involving distributed strains in 'active' and 'passive' zones which could lead ultimately to sliding on shear rupture surfaces. An analysis was developed based on admissible stress fields, with active and passive zones switching about a pivot point, so that the unproped wall could satisfy the conditions of both moment and force equilibrium. (Edited author abstract) 14 refs.

Bolton, M.D. (Cambridge Univ, Engl); Powrie, W. *Geotechnique* v 37 n 3 Sep 1987 p 335-353.

**090300 COLLAPSE OF DIAPHRAGM WALLS.** In this discussion, M.P. O'Reilly, Ove Arup & Partners, discusses what the author noted as the presence of numerous small ruptures at angles of approximately 90-Phi to the main slip surfaces. The clay, as one might expect, given its high overconsolidation ratio, behaves in a rather brittle manner and it is likely that stress concentrations induced by the markers would facilitate the formation of rupture surfaces. Such a clay structure, it may be surmised, will exhibit rupture along surfaces precipitated by these 'stress concentrators'. The author's reply is included.

## Materials

**090301 APPLICATION OF TUBULAR STEEL PIPES AS STRUCTURAL ELEMENTS FOR RETAINING WALLS - PART 2.** In this sequel to the article which appeared in The Dock & Harbour Authority, February 1986, three more examples are given of projects recently implemented in this way, namely a quay wall at Antwerp and two quay walls in Rotterdam. Further, the application of such composite walls, consisting of tubes in combination with two or three Larsen sheet piles is particularly of interest in the case of (drained) construction pits and trenches where, due to a substantial difference of head, water pressure (contrary to what is normally the case with most quay wall structures) plays a dominant role; or where very high demands are made on the stiffness of the structure. (Edited author abstract).

Risselada, J. *Dock Harbour Auth* v 68 n 800 Apr 1988 p 293-297.

## Performance

**090302 LONG-TERM PERFORMANCE OF CANTILEVERED RETAINING WALLS.** This paper addresses the measured performance of four permanent cantilevered wall systems that have been in service for about two years. The continuous profiles of lateral movement with depth, as obtained from inclinometers installed within or directly behind the wall section, are used with beam equation analytical procedures to track the change in active and passive pressure responses with time. The time response of measured lateral movements at the top-of-wall and at the excavation line can be modeled by a rate process theory approach. 14 refs.

**Pressure Effects** See Also WATER WAVES—Pressure Measurement; WATER WAVES—Wind Effects.

**090303 AT-REST TO ACTIVE EARTH PRESSURE TRANSITION.** An approximate analytical procedure is described to estimate the developed lateral earth pressures behind a rigid retaining wall experiencing outward tilt about the base with horizontal cohesionless backfill soil. Included are various stages of wall tilt, starting from an at-rest condition to a full-active condition. The at-rest condition is defined as a stage of no-wall tilt, whereas the full-active condition occurs when the soil elements along the entire depth of the wall are in an active state. The predictions from the developed method of analysis are compared with model test measurements. The comparisons show very good agreement at various stages of retaining wall tilt. Examples are provided to illustrate the transition of the lateral earth pressures behind a smooth and a rough retaining wall. (Edited author abstract) 12 refs.

Bang, S. (South Dakota Sch of Mines & Technology, Rapid City, SD, USA); Kim, H.T. *Transp Res Rec* 1105 1986 p 41-47.

**090304 DYNAMIC EARTH PRESSURES WITH DIFFERENT WALL MOVEMENT MODES.** Dynamic active earth pressures against rigid retaining structures with dry cohesionless backfill are investigated based on the observations of the shaking table model experiment with different wall movement modes: rotation about the base, rotation about the top, translation and a combination of these. The earth pressure distribution, total dynamic thrust, incremental dynamic thrust and their points of application are discussed in detail. It was found that the dynamic active earth pressure distribution is strongly influenced by the wall movement mode particularly at a low level of horizontal acceleration, while inertial body force effect becomes dominant at a high acceleration level. Soil arching developed near the wall top for rotation about the top mode and high residual stress region near the wall base for rotation about the base mode are significantly attributed to the earth pressure distribution. (Edited author abstract) 10 refs.

Ishibashi, Isao (Old Dominion Univ, Norfolk, VA, USA); Fang, Yung-Show. *Soils Found* v 27 n 4 Dec 1987 p 11-22.

**090305 PASSIVE LATERAL EARTH PRESSURE DEVELOPMENT BEHIND RIGID WALLS.** An analytical solution procedure is described to estimate the developed passive lateral earth pressures behind a vertical rigid retaining wall rotating about its toe or top into a mass of cohesionless soil. Various stages of wall rotation, from an at-rest state to an initial passive state to a full passive state, are considered in the analysis. A condition of failure defined by a modified Mohr-Coulomb criterion and equilibrium conditions are used to obtain the necessary equations for solution. The development of friction

along the wall surface at various stages of wall rotation is also taken into account in the analysis. Finally, the results predicted by the developed method of analysis are compared with those obtained from the experimental model tests on loose and dense sand. The comparisons show good agreements at various stages of wall movement. (Author abstract). 10 Refs.

## Stability

**090306 PARAMETRIC STUDY OF THE STABILITY OF EMBEDDED CANTILEVER RETAINING WALLS.** In the design of an embedded earth retaining structure the geometry is adjusted to achieve a prescribed factor of safety against overturning. There are at present a number of methods which can be used to assess the stability of an embedded retaining wall, each of which gives a different value of the factor of safety for a stable wall configuration. To achieve a measure of consistency in the design of this type of structure, information is therefore needed on the interrelations between the methods. This report gives results from a parametric study which used four different methods to assess the stability of an embedded cantilever wall retaining 5 metres of ground. The effect on the factors of safety of variations in individual input parameters is illustrated and the findings compared with the values of factor of safety currently recommended for design. (Author abstract) 13 refs.

Symons, I.F. (TAISEI Corp, Yokohama, Jpn); Kotera, H. *Res Rep Transp Road Res Lab* 116 1987 15p.

**090307 LATERAL STABILITY OF COMPRESSIBLE WALLS.** The author has shown how the compressibility of a retaining wall may affect its stability. Wall settlements relative to fill can produce a shear reversal at the soil-wall interface which modifies the inclination of the active pressure. The tangential component of the resultant at the wall base increases whereas the normal one decreases. The factor of safety against sliding decreases accordingly. There may be some other reasons for lateral stability reductions related to underlying soil compressibility and wall stiffness. As an example, the case of large lateral displacements of a harbour quay is briefly described in this discussion. The author's reply is included. 1 Ref.

O'Rourke, T.D. *Geotechnique* v 38 n 2 Jun 1988 p 317-318.

## Structural Analysis See Also COASTAL ENGINEERING—Research.

**090308 DISPLACEMENT DEPENDENT EARTH PRESSURES.** The method of designing retaining walls is incomplete without displacement criteria and the bulk of literature available on earth pressures does not consider this aspect. In the present study, a simple and sufficiently accurate analysis has been proposed to find the variation of earth pressure with wall displacement when wall undergoes translation, rotation about bottom and rotation about top in active and passive conditions. The analysis also gives pressure distribution for any displacement under any mode of wall movement and for both active and passive conditions. The presented results of parametric study and their comparison with reported experimental results reveal the effectiveness of the analysis. (Author abstract) 12 refs.

## Structural Design

**090309 BEHAVIOR OF EMBEDDED CANTILEVER RETAINING WALLS - THE RESULTS OF A FINITE ELEMENT STUDY.** The design of cantilever retaining walls is based on approximate limit equilibrium calculations which assume a point of zero movement

occurs at some depth near the toe of the wall. This paper describes the results of a finite element study to check the validity of this technique. The accuracy of the calculated embedment is checked, and the influence of parameters such as initial soil stress and construction procedure is evaluated. An elasto-plastic constitutive law is used to model soil behavior. Results indicate that the limit equilibrium method gives a very reasonable estimate of the embedment depth required to ensure stability. The maximum bending moment calculated using this technique was found to be greater than the corresponding values from the finite element analyses. Some reduction in bending moment, as calculated by the limit equilibrium method, may therefore be warranted. (Edited author abstract) 3 refs.

## Reduction

**090312 SPECIAL FEATURES OF CATHODIC RHENIUM REDUCTION FROM ACIDIC PERRHENATE SOLUTIONS.** Despite the large amount of work that has been done in cathodic rhenium reduction, different and sometimes even contradictory opinions exist as to the effect of solution acidity on the mechanism of rhenium reduction. An attempt was made to define more accurately the role of hydrogen ion concentration in cathodic rhenium reduction. The dependence of perrhenate reduction rate on  $pH_0$  was found to exhibit two distinct maxima at similar  $pH_0$ -values. They were attributed to two mechanisms of cathodic rhenium reduction

from aqueous perrhenate solutions and to a nonequilibrium change in ionic composition of the region at the cathode which occurs as the cathodic process actually proceeds. (Edited author abstract) 16 refs.

**090313 INTER- AND INTRAMOLECULAR EXCITED-STATE INTERACTIONS OF SURFACTANT-ACTIVE RHENIUM(I) PHOTOSENSITIZERS.** A new series of surfactant-active complexes of the form  $[(bpy)Re(CO)_3NC(CH_2)_nCH_3]^+$ ,  $n = 0-17$ , have been synthesized and characterized. These complexes exhibit a unique intramolecular perturbation of their excited-state manifold by the normally passive alkyl chain. Intramolecular fold back, a strong function of chain length, alters the solvent environment around the excited portion of the molecule with a concomitant change in the state energies and decay paths. Molecular models, cyclodextrin binding studies, absorption and emission spectroscopy, excited-state lifetime measurements, and oxygen-quenching studies support this model. The alkyl chain can function as a molecular switch and invert the lowest excited states in the molecules at low temperature. Energy level diagrams are developed that explain both room-temperature and 77 K results. (Author abstract). 46 Refs.

## Thin Films

**090314 SOME PROPERTIES OF  $ReSi_2$ .** Thin films of  $ReSi_2$  were prepared by the co-evaporation of rhenium and silicon. The structure of the films is compared with the previously reported structure of this compound. The resistivity and Hall coefficient of the films were measured from 4.2 K to 523 K. Optical transmission measurements were also carried out. The films display semiconducting properties (p-type) characteristic of a small band gap, in agreement with measurements reported for bulk and single-crystal samples. The discrepancy between these results and recent band calculations, indicating a potentially high conductivity, is briefly discussed. (Author abstract). 45 Refs.

## RHENIUM PLATING

**090315 PULSED ELECTRODEPOSITION OF RHENIUM.** In pulse plating, two diffusion layers are formed, comprising a pulsating layer adjacent to the cathode and a stationary layer extending to the bulk of the electrolyte. Using very short pulses the pulsating layer remains very thin; hence the concentration gradient is very high, allowing the application of very high current densities during the pulse without exceeding the mass transport limitation. Since increase of current density appears to favor improved properties to electrodeposited rhenium, pulse plating thus offers interesting possibilities in this context. 9 refs.

Puippe, J.C.I. *Theory and Pract of Pulse Plating* Publ by American Electroplaters & Surface Finishers Soc, Orlando, FL, USA, 1986 p 177-187.

**090316 STRUCTURE AND X-RAY DENSITY OF ELECTROCHEMICALLY DEPOSITED RHENIUM FILMS.** The formation of masking coatings is one of the problems that arise during the preparation of x-ray patterns. Local electrodeposition of heavy metals is used primarily for this purpose. The electrodeposition of rhenium was carried out at a constant cathode current density and room temperature. The investigations conclude that electrochemically deposited rhenium films can be used as a material for the masking coatings of x-ray patterns since the absorption coefficients of the x-ray radiation of the films are superior to traditionally employed materials and surpass them in terms of corrosion resistance and simplicity of production. 4 refs.

**090318 CONSIDERATION OF THE YAMAMOTO NETWORK THEORY WITH NON-GAUSSIAN CHAIN SEGMENTS.** The molecular network theory due to Yamamoto has been considered, and the effect of modeling the network segments as non-Gaussian chains has been investigated. By using a non-Gaussian free energy expression for the entanglement creation function and a constant breakage function, one finds that the resulting material functions will depend on the number of subunits in the network segments. For short segments, an initial increase with shear rate occurs in the viscosity. Introduction of a slip coefficient to remove the affine deformation assumption results in shear thinning behavior, which becomes more pronounced for long polymer segments. Depending on the network segment length and the slip coefficient, it is shown that our choice of entanglement creation and destruction functions leads to the results of Lodge's theory for affine non-Gaussian chains on one hand, and to Fuller and Leal's predictions for non-affine Gaussian chains on the other. (Edited author abstract) 10 refs.

**090322 STUDY OF IMPACT INTERACTION BETWEEN COMMUTATING CONTACTS AS FUNCTION OF THEIR SURFACE FINISH.** Deformations of contacting bodies in commutating devices considering magnitudes of their kinetic energy are commensurable with asperities dimensions on their surfaces (specified by state standard GOST 2789-73). This fact calls for consideration of surface roughness in the analysis of contact closing. A dynamic collision model is based on an elasto-plastic rheological model of colliding bodies. This model conforms to the results of experimental studies. An elasto-plastic model of the material near contact zone is transformed into a non-linear elasto-plastic mathematical model of the given collisions. 2 refs.

Theory

**090325 CONSTITUTIVE EQUATION INCLUDING COMPRESSIBILITY EFFECTS.** Rheological theory including volume (compressible) effects is important in a practical sense in that many polymer processes involve rapid cooling to a final, typically nonequilibrium, glassy state. There are also compressible effects in the sense of Poisson's ratio - that is, deformation-induced volume changes occur even at constant temperature. In earlier work we (Snow and Bogue) set down a generalized constitutive equation which includes these various effects. The integral statement there is quite complicated, however, and is difficult to execute except in the simplest deformations. The present work is a restatement of the prior formulation in a more tractable and slightly modified form. (Author abstract) 22 refs.

Thermal Effects See POLYMERS—Rheology.

Thin Films

**090326 PROCESSING AND CHARACTERIZATION OF CELLULOSE TRIACETATE FILMS FROM ISOTROPIC AND LIQUID CRYSTALLINE SOLUTIONS.** The work reported here is motivated by two factors: the awareness that CTA can form lyotropic liquid crystals having the possibility of controlled structure and an interest in films that have properties derived from being processed through an intermediate liquid crystalline state. Thus a process was developed to fabricate films and then characterize and study the properties of these films. To this end then we report on the film fabrication process and some rheological experiments; permeation studies of the films; and SAXS, SEM, DSC, WAXS, mass density, birefringence and mechanical characterization of these films. 21 refs.

## Analysis

**090328 ANALYSIS OF A NEWLY DEVELOPED DAMPED-OSCILLATION RHEOMETER: NEWTONIAN LIQUID.** The behavior of a newly developed damped-oscillation rheometer was analyzed for Newtonian liquids from both theoretical and experimental points of view. This rheometer consists, essentially, of a cylindrical tube suspended from a torsion wire that is filled with the liquid to be tested. In order to determine the relationship between the rheological parameters of the liquid and the period or the logarithmic damping factor measured by this rheometer, a Newtonian liquid was considered as a first test liquid. Based on various assumptions, the equations of motion for the liquid and the cylindrical tube were solved simultaneously. Numerical solutions and approximate analytical solutions valid for certain ranges of the parameters were obtained. The results are compared with experimental results which we measured using this rheometer. (Author abstract) 2 refs.

## Applications

**090329 ASSEMBLY AND USE OF A COMPUTERIZED TORQUE RHEOMETER.** The personal computer has started a revolution in the way data is collected and stored by bringing computer capabilities within the economic reach of even the smallest company. Computer data acquisition and manipulation expands the usefulness of the already valuable torque rheometer as a tool for both rheological studies and routine quality control testing. Analysis of more fundamental rheological properties than just the traditional torque vs. time curve is possible without the time consuming manual data manipulation. Data storage and recall of routine or Q.C. testing for accurate comparisons of results is made easier. Torque rheometer uses made easier by the use of a computer are reviewed. Also given are details of how to hook up a personal computer to an existing torque rheometer. (Author abstract) 21 refs.

## Strain

**090330 CONTROL OF STRAIN RATE IN A SHEET-INFLATION RHEOMETER.** In the experimental study of nonlinear viscoelasticity, it is found that a material's response depends on the size, rate, and kinematics of the deformation. While uniaxial extension is now fairly widely used in the study of polymeric liquids, there has been less success with the generation of controlled, uniform, biaxial extension. Several methods have been used to generate this type of deformation. The earliest was the sheet inflation technique, which has been used to study raw elastomers, rubbery thermoplastics and bread dough. The problem of controlling the strain rate has limited its application to such materials. The sheet inflation techniques may still be the most attractive basis for a simply performed test that can yield meaningful data on a wide range of materials, including molten thermoplastics. The authors address the problem of controlling the strain in such a way as to maintain a constant strain rate. 17 refs.

## Theory

**090331 BOUNDARY EFFECTS ON THE DRAG OF AN OSCILLATING SPHERE: APPLICATIONS TO THE MAGNETIC SPHERE RHEOMETER.** The effect of a closed, nearby boundary on the drag of a small, oscillating sphere in an incompressible, linearly viscoelastic medium is studied. Through a perturbation procedure the functional dependence of the drag on the complex oscillatory Reynolds number is determined and shown to differ from that of the unbounded case. These results allow one to account for boundary effects in the determination of the complex viscosity using the magnetic sphere rheometer. This paper is motivated by the rheological study of materials purified in minute quantities such as intracellular protein, thus the need for small chamber sizes for use with the rheometer and the need for boundary corrections for the drag. (Author abstract) 18 refs.

## Extraction

**090332 EXTRACTION OF RHODIUM FROM AQUEOUS NITRIC ACID BY DINONYLNAPHTHALENE SULPHONIC ACID.** The extraction of rhodium from aqueous nitric acid using dinonylnaphthalene sulfonic acid has been investigated. The extraction occurs readily from 0.1M to 1.0M nitric acid and, since the rhodium is extracted as  $[Rh(H_2O)_6]^{3+}$  into the inverted micelles of the organic solution, equilibration times are less than 5 minutes. Extraction is enhanced by the addition of nitrite ion to form  $[Rh(H_2O)_5NO_2]^{2+}$  as the extracted species. (Author abstract) 18 refs.

**090342 CRUSHING AN ELASTIC-PERFECTLY PLASTIC RING BETWEEN TWO POINT LOADS.** A thin ring with elastic-perfectly-plastic moment curvature relation is crushed by two point loads. The non-linear governing equations are solved by perturbations and numerical integrations. It is found that the ring may have none, one or two pairs of plastic hinges depending on the normalized force and  $\lambda$ , a non-dimensional parameter characterizing plasticity. Sudden collapse of the ring is possible. Partial spring-back due to irreversibility is determined. (Author abstract). 8 Refs.

**Design** See SPACE SHUTTLES—Equipment.

### Elasticity

**090343 ON THE CONSTRAINED ELASTIC RING.** The problem of a thin elastic ring contained within a smooth rigid cavity is considered for the case where the ring is subjected to a radial point load. The problem is approached as a moving intermediate boundary problem in the calculus of variations and a closed-form analytical solution is obtained. Numerical results are presented for several cases, revealing unstable behavior of the ring configuration. (Author abstract) 9 refs.

### Failure

**090344 UNRESTRAINED OUT-OF-PLANE BUCKLING OF MONOSYMMETRIC RINGS.** Rings which are loaded by a uniformly distributed radial inward load may buckle out of the plane of the ring. This paper is concerned with out-of-plane buckling of rings of monosymmetric section with the axis of symmetry oriented radially. It is assumed that there are no restraints against buckling displacements. A new solution to the problem is derived and compared extensively with existing analytical solutions and finite element analysis. All the existing solutions are shown to be either limited in application or in error. The new solution compares well with finite element analyses, provided there is no distortion of the cross-section. (Author abstract) 10 refs.

Teng, J.G. (Univ of Sydney, Aust); Rotter, J.M. *Res Rep Univ Sydney Sch Civ Min Eng* n R536 Dec 1986 40p.

### Forging

**090345 INCREMENTAL FORGING FOR THE PRODUCTION OF RING-SHAPED COMPONENTS.** Incremental forging of the ring blanks allows to purposefully control the flow of material at substantially reduced deformation power and to produce ring blanks in a wide dimensional range. An analysis of the elementary theory and of the tests made in an integrated open-die forging plant has shown the existence of definite relationships between the forging parameters and the geometry of the ring produced, and the possibility of appropriately controlling the flow of material. Incremental forging allows thus both to expand and reduce the inside diameter and to optimize the initial rings for the ring rolling process. It makes it possible, moreover, to produce rings with discontinuous sections, e.g. with too-things. The application of incremental forging results thus in a considerably higher flexibility of the production process. (Author abstract) In German with English abstract. 11 refs.

### Materials

**090348 PRODUCTION OF TEFLON SHEATHS FOR RUBBER RINGS WITH CIRCULAR CROSS SECTION.** To improve the reliability of the entire seal and to reduce expenditure of scarce material, a new method of making Teflon sheaths was developed. The technology of making the sheaths consists of the following: The Teflon blank is mounted in the lathe chuck and the end face is undercut. Then the blank is turned to the specific diameter. With a view to the cross-sectional diameter of the rubbish ring, grooves are turned along the blank at the distance  $1 = k \cdot r_d$  from each other. When the operation is finished, a rubber ring is slipped over the blank, and it is aligned by the forming tool mounted in the tool holder. The tool must have a sharp cutting edge and a forming front face made in the shape of a torus with radius  $d/2 +$  thickness of the sheath. The Teflon sheath can also be formed without the rubber ring. 4 refs.

### Mathematical Models

**090349 DYNAMIC RESPONSE OF A ROTATING THICK RING TO FORCE OR DISPLACEMENT EXCITATION.** The dynamic response of a rotating thick ring is obtained, subjected to either force or displacement excitation. The equations of motion are formulated in an inertial reference frame, with account taken of ring extensibility, transverse shear, rotatory inertia, rotation, initial stress due to pressure loading and an elastic foundation. A receptance approach is utilized for obtaining the solutions. These receptances have the special property of not following reciprocity because of Coriolis effects. Critical speeds corresponding to zero natural frequencies as observed in the inertial reference frame are found in free vibration. The damping effects on the forced vibrations are studied by using a structural damping model. The dynamic responses to different force or displacement excitations are compared. In particular, a tangentially constrained displacement excitation is investigated that can result in a considerable reaction torque to the ring support. (Author abstract) 9 refs.

### Oscillations

**090351 INFLUENCE OF INTERNAL RESONANCE ON THE NON-LINEAR OSCILLATIONS**

**OF A CIRCULAR RING UNDER PRIMARY RESONANCE CONDITIONS.** An accurate set of equations of motion, developed previously by the authors, is used to analyze the large amplitude forced oscillations of a thin circular ring. Qualitative and quantitative information about the primary response of a ring subjected to either a distributed harmonic in-plane or a distributed harmonic out-of-plane load is obtained by the method of multiple scales. The response due to the in-plane excitation or a ring in the presence of an internal resonance indicates that purely planar oscillations are unstable over a major portion of the primary resonant peak, and that nonplanar oscillations exist over certain ranges of excitation frequencies. For certain values of excitation frequencies, the presence of unsteady motions with no exchange of energy between the in-plane and the out-of-plane modes is indicated. Internal resonance is shown to have no effect on the primary resonant peak due to the out-of-plane excitation. However, over certain other ranges of excitation frequencies, the in-plane bending mode is also excited (at the same order) and the resulting response is non-planar. (Edited author abstract) 13 refs.

## Pressure Effects

**090352 MECHANISM ANALYSIS OF THE POST-BUCKLING RESPONSE OF A CIRCULAR RING UNDER EXTERNAL PRESSURE.** Of recent interest, in the context of pipeline designs, is how the plastic post-buckling pressure collapse sequence of a circular ring may be related to the approximation of the propagation pressure. A simple rigid plastic mechanism analysis, incorporating strain-hardening effects, is presented for the analysis of the plastic post-buckling response of a circular ring under external pressure. Results are found to compare favourably with those obtained through more elaborate studies. (Edited author abstract). 5 refs.

## Strain See FLYWHEELS—Stresses.

## Stresses See Also STRUCTURAL DESIGN—Stresses; TIRES—Radial.

**090353 ON TORSION AND SHEAR IN A RING SECTOR.** The shear stresses in a ring sector of circular cross-section were determined by O. Goehner using a method which takes into account a twisting moment. However, this method does not consider the stress field produced by a shear force which also acts on every cross-section. The present paper extends the method of Goehner by considering this shear force. The stress function introduced by Goehner is modified to include a term which contains a stress correction coefficient K. The stress equations containing K do not contribute to the moment equation, so such terms agree exactly with Goehner's solution. The correction coefficient K, though physically significant, is small. Four terms are developed in the series solution, by the method of successive approximation. (Edited author abstract) 5 refs.

**090354 OUT-OF-PLANE BUCKLING OF RESTRAINED MONOSYMMETRIC RINGS.** Rings are commonly used at junctions between shell segments in pressure vessels, tanks and silos. Often the ring is in circumferential compression and is susceptible to failure by buckling. This buckling is usually restrained by the adjacent shell segments, which prevent translation and elastically restrain rotation of the point of attachment. The ring is normally not loaded at its centroid or shear center. This paper presents an analysis of the buckling of a monosymmetric ring under these conditions. Four versions of the theory are presented, which make progressively less restrictive assumptions relating to the ring as a

'thin ring'. The analytical predictions are compared with numerical stability assessments from a finite element shell buckling analysis. (Edited author abstract) 15 refs.

Teng, J.G. (Univ of Sydney, Aust); Rotter, J.M. *Res Rep Univ Sydney Sch Civ Min Eng* n R510 Oct 1985 61p.

**090355 TRANSIENT THERMAL STRESS ANALYSIS OF CIRCULAR CERAMIC RINGS.** Structural ceramics are the materials most expected to realize improvements in the efficiency and reliability of heat engines. This report presents a transient thermal stress analysis of circular ceramic rings, the inner and outer boundaries of which are heated by a hot environment through a given heat transfer. Taking four kinds of ceramics, silicon nitride, silicon carbide, zirconia and alumina, it focuses on how the material characteristics of those ceramics influence the thermal stresses which arise in the circular ceramic rings. Since the temperature distribution depends on the thermal conductivity and stress components, a quantity  $\alpha E T$  (product of thermal expansion coefficient, Young's modulus and temperature), the computed results show that the maximum values of thermal stress in the zirconia and alumina rings are considerably higher than the ones in the silicon nitride and silicon carbide rings. (Author abstract) In Japanese. 8 refs.

Amada, Shigeasu. *Nippon Kikai Gakkai Ronbunshu A Hen* v 54 n 500 Apr 1988 p 616-620.

**090356 STUDY OF THE STRESSED STATE OF AN ORTHOTROPIC RING ON THE BASIS OF VARIOUS THEORIES.** In an exact statement and in terms of approximate theories (classical theory, Timoshenko theory, and a refined theory suggested by one of the authors), the stressed-strained state is studied of an orthotropic ring of a medium thickness acted upon cyclically by a symmetrical ring with two types of loading are described. (Author abstract). 4 Refs.

## Structural Analysis

**090359 UNRESTRAINED OUT-OF-PLANE BUCKLING OF MONOSYMMETRIC RINGS.** Rings which are loaded by a uniformly distributed radial inward load may buckle out of the plane of the ring. This paper is

concerned with out-of-plane buckling of rings of monosymmetric section with the axis of symmetry oriented radially. It is assumed that there are no restraints against buckling displacements. A new solution to the problem is derived and compared extensively with existing analytical solutions and finite element analysis. All the existing solutions are shown to be either limited in application or in error. The new solution compares well with finite element analyses, provided there is no distortion of the cross section. (Author abstract) 12 refs.

Teng, J.G. (Univ of Sydney, Aust); Rotter, J.M. *J Constr Steel Res* v 7 n 6 1987 p 451-471.

**090360 CONTRIBUTION TO THE OPTIMAL NUMBERING OF A RING STRUCTURE.** An optimal element numbering of a pipeline system containing rings is considered. In order to minimize the front width two possible cases of ring structure are analysed and solved in different manners. An example is shown of a typical one having both types of rings. By applying the automatic procedure for element numbering, the front width can be reduced by approximately 40%. The algorithm and FORTRAN 77 programme are presented, as well as input and output data for the example. (Author abstract) 1 ref.

Marjanovic, Ljiljana (Univ of Belgrade, Belgrade, Yugoslavia); Sedmak, Aleksandar. *Comput Struct* v 28 n 5 1988 p 573-578.

**090361 BUCKLING OF RINGS IN COLUMN-SUPPORTED BINS AND TANKS.** This paper deals with the out-of-plane buckling of annular plate rings in column-supported bins and tanks. The stress distributions in such rings are first examined using a finite element shell analysis. A closed-form solution for the buckling of rings under non-uniform circumferential stresses is then derived. Numerical results from the closed-form solution are compared with those from a finite element shell buckling analysis, and close agreement is found. The significant effect of stress non-uniformity on the buckling predictions is demonstrated. Finally, simplified equations are given which are suitable for structural design purposes, and which closely model the predictions of the more rigorous solution. (Edited author abstract) 25 refs.

Teng, J.G. (Univ of Sydney, Sydney, Aust); Rotter, J.M. *Res Rep Univ Sydney Sch Civ Min Eng* R 552 Sep 1987 35p.

**090362 BUCKLING OF RESTRAINED MONOSYMMETRIC RINGS.** Rings are commonly used at junctions between shell segments in pressure vessels, tanks, and silos. Often the ring is in circumferential compression and is susceptible to failure by buckling. This buckling is usually restrained by the adjacent shell segments, which prevent translation and elastically restrain rotation of the point of attachment. The ring is normally not loaded at its centroid or shear center. This paper presents an analysis of the buckling of a monosymmetric ring under these conditions. Four versions of the theory are presented, which make progressively less restrictive assumptions relating to the ring as a 'thin ring.' The analytical predictions are compared with numerical stability assessments from a finite element shell buckling analysis. The classical thin ring solution is shown to be satisfactory for most practical purposes. (Author abstract). 15 Refs.

## Testing See Also DOMES AND SHELLS—Buckling.

**090363 WERKSTOFFPRUEFUNG AN MASSGEPRESSTEN KOHLENSTOFF-RINGEN.** [Material Testing on Molded-to-Size Carbon Rings]. In order to characterize molded-to-size carbon seal rings, it is important to determine the flexural strength and Young's modulus. The common, small diameter-shapes, however, do not allow to cut test beams from fabricated parts. Therefore, the 'C-ring-test' is used. The given calculation method remains valid for generally 'symmetric' cross-sections and for strongly curved beams up to a ratio

radius/ring thickness  $\geq 1$ . Only increasing asymmetry is accompanied by greater deviations from the calculated data. The results from the well-known 3-point-test for straight bars lead to the same material data as those from the 'C-ring-test'. (Edited author abstract) In German. 10 refs.

## Vibrations

**090364 RESPONSE OF ROTATING RINGS TO HARMONIC AND PERIODIC LOADING AND COMPARISON WITH THE INVERTED PROBLEM.** The harmonic and periodic forced vibrations of rotating rings are derived and investigated. The modal expansion technique yields the forced solution, which is characterized by four generalized co-ordinates associated with each  $n$  (circumferential wave number). The inextensional assumption is presumed, when flexural vibration is the only important component, to reduce the order to the system. The closed form solutions to the harmonic load cases, once concentrated, once distributed, are demonstrated and interpreted. The approach is then extended to periodic loads, where Fourier sine and cosine series is applied. Examples depict the numerical responses to all the cases being derived. The solutions of a stationary ring subjected to traveling loads are also solved for comparison. Their difference is investigated and interpreted from various viewpoints. (Author abstract) 15 refs.

Huang, S.C. (Purdue Univ, West Lafayette, IN, USA); Soedel, W. *J Sound Vib* v 118 n 2 Oct 22 1987 p 253-270.

**090365 EIGENVALUES OF RINGS WITH RADIAL SPRING ATTACHMENTS.** Natural frequencies and modes of a circular ring deviating from axisymmetry due to multiple radial springs are obtained by utilizing the natural frequencies and modes of the axisymmetric ring. The problem of a non-axisymmetric ring due to an unlimited number of radial spring connections is formulated in a general form. Numerical results are presented for up to three radial spring connections. This is of practical interest since radial stiffness variations exist in many complicated structures such as tires. (Author abstract) 23 refs.

**090366 PHASE VELOCITY OF A PRESSURE WAVE ON THE AXIS OF AN ACOUSTIC FIELD OF A CIRCULAR RING IN AN ACOUSTIC Baffle.** This paper is concerned with the so-called local velocity of a harmonic pressure wave of a circular ring vibrating with a constant velocity amplitude. The ring is placed in an infinite rigid acoustic baffle. The local propagation velocity was calculated on the axis conducted from the center of the ring perpendicularly to its surface. The propagation velocity changes from infinity for  $z = 0$  (singular point) to a constant value,  $c_0$ , for  $z$  equal to about 10 times the external radius of the ring. (Author abstract) 6 refs.

**090367 ON GENERAL IN-PLANE VIBRATIONS OF ROTATING THICK AND THIN RINGS.** Complete sets of equations of motions for general in-plane vibrations of rotating thick and thin rings on elastic foundations are derived. The thick ring theory takes account of the effects of extensibility, transverse shear, rotary inertia and rotation, as well as the effects of initial stresses due to pressure loads and centrifugal force. The consistency of the formulation is demonstrated by reducing it to classical ring theories based on inextensional or negligible shear deformation assumptions. Predictions of frequencies for bending and extensional type vibrations are close to experimental data for non-rotating thick rings. It is argued that inextensional assumptions in thick ring theories are

improper because extensional coupling effects are as important as shearing effects, especially for the rotating ring. The correct quadratic displacement terms in the strain-displacement relations, necessary for the complete description of initial stress effects, are discussed. (Edited author abstract) 19 refs.

**090368 POTENTIAL APPLICATIONS OF FUZZY SETS IN INDUSTRIAL SAFETY ENGINEERING.** This paper discusses potential applications of fuzzy set theory to risk analysis in the area of industrial safety engineering. Vagueness and imprecision in mathematical quantification of risk are equated with fuzziness rather than randomness. The concept of risk evaluation, using linguistic representation of the likelihood of the occurrence of a hazardous event, exposure, and possible consequences of that event, is proposed. The approximate reasoning technique based on fuzzy logic is used to derive fuzzy values of risk. (Author abstract) 39 refs.

**090369 APPLICATIONS OF THE GENERALIZED BIAS OPERATOR FOR UNCERTAINTY ANALYSIS.** A new uncertainty analysis method based on the generalized bias operator method is presented. The new method can be used for those cases in which the other uncertainty analysis methods cannot be applied, due to the lack of or the incomplete knowledge about the input parameter's uncertainties, or due to an inadequate model. The method presented can be applied in those cases in which at least one of the system's responses is measured and the accuracy of the measurements is better than the deviation between the measured and the calculated value obtained. The theory of the method is presented, as well as methods to obtain the special sensitivity matrices associated with the method. (Author abstract) 4 refs.

**090370 PROBABILITY DISTRIBUTIONS AND THEIR PARTITIONING.** The partitioned multiobjective risk method (PMRM) was developed for solving risk-based multiobjective decisionmaking problems. Based on the premise that the expected value concept is not sufficient for proper decisionmaking, the PMRM generates a number of conditional expected value functions (or risk functions) by partitioning the probability axis into probability ranges. The goal of partitioning the probability axes is to have better information on extreme events for decisionmaking purposes. These conditional expectations are dependent on the chosen partitioning points. This paper analyzes how conditional expectations are sensitive to variations in partitioning. One of the risk functions is a measure of extreme and catastrophic events. By using the relationship between this particular risk function and the statistics of extremes the sensitivity analysis is simplified. In many practical applications, it is difficult to determine which type of distribution function best represents the random process. (Edited author abstract) 12 refs.

**090371 COMPARISON OF FORMULAE FOR PREDICTING RAIL-HIGHWAY CROSSING HAZARDS.** New models for assessing the need for improvements have been developed, and five models were evalu-

ated: the U.S. Department of Transportation (DOT), Peabody-Dimmick, NCHRP Report 50, Coleman-Stewart, and New Hampshire - were evaluated using a data base maintained by the Virginia Department of Highways and Transportation. In addition, the performance of the methods for predicting the EAR were compared by using the chi-square test and the power factor. The results indicated that the DOT formula outperformed the other four methods in both the evaluative and comparative analyses, and thus were recommended for use. The priority list produced by this formula is only one criterion used in determining the need to improve conditions at any crossing. (Edited author abstract) 1 ref.

Faghri, Ardeshir (Dep of Highway & Transportation, Charlottesville, VA, USA); Demetsky, Michael J. *Transp Res Rec* 1114 1987 p 152-155.

**090372 APPLICATIONS OF RISK ASSESSMENT TECHNIQUES TO HAZARDOUS WASTE MANAGEMENT.** Applications of risk assessment techniques to hazardous waste management are briefly discussed in terms of selecting appropriate waste management technologies assessing operating sites, setting priorities for clean up of problem sites, determining the appropriate level of clean up and planning new facilities. A specific case history involving risk assessment for the siting of a waste management facility in the Province of Ontario, Canada is described in more detail. Risk estimates are provided for exposure via inhalation and ingestion of potentially contaminated local water, crops, meat and milk. The predicted risk are compared to risks of death from selected voluntary and involuntary exposures. (Author abstract) 8 refs.

Scott, Michael P. (Environmental Resources Ltd, London, Engl). *Waste Manage Res* v 5 n 2 Jun 1987 p 173-181.

**090373 HANDLING OF ACCEPTABLE RISKS.** This paper examines some of the problems associated with the handling of risk and, in particular, the arguments that may be deployed in favour of reducing particular forms of risk. The paper suggests that, whilst risk can always be reduced, the costs involved vary enormously in terms of benefits achieved. Governments should be concerned to maximize overall risk reduction for any given level of expenditure. To treat each risk separately and independently can lead to a non-optimal allocation of resources. (Author abstract). 8 refs.

## Agricultural Applications

**090374 ANALYSIS OF DAMAGE OF U.S. SOYBEAN YIELDS FROM 1982 ACID DEPOSITION LEVELS.** Experimental data were compiled for seven soybean varieties studied at four different locations in the U.S. for a period of one to three years. Three dose-response functions (linear, quadratic, and Weibull) were fitted, as appropriate, to the experimental data. Effects of acid deposition on soybean yields were estimated by combining variety-specific dose-response and production data. These calculations suggest that U.S. soybean production (2.2 billion bushels in 1982) would increase by 3.2 million bushels with a 10% reduction in 1982 hydrogen ion concentration levels in all counties where soybeans were grown, and by almost 70 million bushels with uniform improvement to pH 5.2. These estimates are based on many simplifying assumptions and are subject to several important sources of uncertainty explored in this study. The calculated changes are small in comparison with effects from other natural and anthropogenic stresses. (Author abstract) 32 refs.

## Analysis

**090375 DESIGN-SAFETY ENHANCEMENT THROUGH THE USE OF HAZARD AND RISK ANALYSIS.** The application of qualitative and quantitative hazards/risk analysis methods is discussed. Two examples of both qualitative and quantitative methods are discussed. The relative advantages of each, as well as relative manpower requirements for their application, are examined. The two qualitative analysis examples are: 1) hazards and operability (HAZOP) analysis, based on the conceptual design analysis of an offshore gas-processing platform, and 2) a qualitative fault-tree analysis based on a design review of a land-based oil-processing facility. The two quantitative analysis examples are: 1) the use of event sequence diagrams (ESDs) for the risk analysis of a batch chemical-operation plant, and 2) an event-tree analysis relative to the consequences of the loss of electric power for the same batch plant. In these examples, design operations and maintenance-safety enhancements that have been implemented are identified. 7 refs.

**090376 HOW TO IMPROVE THE EFFECTIVENESS OF HAZARD AND OPERABILITY ANALYSIS.** The key elements that make the hazards and operability (HAZOP) technique effective for identifying chemical process hazards are outlined. Six categories of problems that can sometimes reduce the effectiveness of HAZOP and even prevent it from discovering some major hazards are explained. Several examples are included to show how lack of experience, failure to communicate, management shortcomings, complacency and poor loss-prevention practices, a shortage of technical information, and other limitations, each contribute to the problem. Practical solutions are recommended for countering the difficulties and for making the HAZOP a more effective risk-management tool. 6 refs.

**090377 ESTIMATION OF LONG-TERM RISK FROM CANADIAN URANIUM MILL TAILINGS.** A methodology is presented for assessing the risk from Canadian uranium mill tailings piles. The methodology is based on the 'set of triplets' concept and uses an event tree to identify various scenarios representing the performance of a pile over its 1,000-year design life. Compartment-type mathematical models are used to quantify the movement of hazardous substances through the environment. Numerical examples are given of both 'level 1' (straight probabilistic) and 'level 2' (probability of frequency) type analyses. (Author abstract) 10 refs.

*Risk Anal* v 7 n 3 Sep 1987 p 287-298.

**090378 ESTIMATED SOIL INGESTION RATES FOR USE IN RISK ASSESSMENT.** Assessing the risks to human health posed by contaminants present in soil requires an estimate of likely soil ingestion rates. In the past, direct measurements of soil ingestion were not available and risk assessors were forced to estimate soil ingestion rates based on observations of mouthing behavior and measurements of soil on hands. Recently, empirical data on soil ingestion rates have become available from two sources (Binder et al., 1986 and van Wijnen et al., 1986). Although preliminary, these data can be used to derive better estimates of soil ingestion rates for use in risk assessments. Estimates of average soil ingestion rates derived in this paper range from 25 to 100 mg/day, depending on the age of the individual at risk. Maximum soil ingestion rates that are unlikely to underestimate exposure range from 100 to 500 mg. A value of 5,000 mg/day is considered a reasonable estimate of a maximum single-day exposure for a child with habitual pica. (Author abstract) 12 refs.

LaGoy, Peter K. (ICF-Clement Associates Inc, Washington, DC, USA). *Risk Anal* v 7 n 3 Sep 1987 p 355-359.

**090379 CHEMICAL HEALTH EFFECTS ASSESSMENT METHODOLOGY FOR AIRBORNE CONTAMINANTS.** Chemical Health Effects Assessment Methodology (CHEM) is a new procedure for assessing hazardous properties of airborne toxic contaminants. CHEM evaluates substances for four major health effect categories: carcinogenicity, mutagenicity, reproductive/developmental toxicity, and toxic effects other than the first three. Three elements are considered in the assessment: weight of evidence, potency, and severity of effect. This approach produces a profile of toxic properties of chemicals which preserves their unique multidimensional character and highlights data gaps. (Author abstract) 19 refs.

**090380 HAZARD, RISK AND PLANNING.** During the last two decades the process industries overseas have evolved systematic and powerful techniques for identifying process hazards. Five activities need to be completed in adequate detail. The first four need to be addressed by the industry in evolving a development application and the fifth needs to be addressed by the local authority in concert with the public. They are: 1. Hazard identification. 2. Equipment and system failure frequency estimates. 3. Consequence calculations. 4. Overall estimation of risk. 5. Assessment of acceptability. A discussion is presented of equipment and system failure frequency estimates, consequence calculations, estimation of risk, and assessment of acceptability.

**090381 EXPERT OPINION USE FOR PROBABILITY ASSESSMENT IN SAFETY STUDIES: MAIN TOPICS AND ELEMENTS OF AN APPLICATION-ORIENTED RESEARCH PROGRAM.** Current probability assessment approaches are almost exclusively based on failure data as stored in a limited number of databases. Associated with these databases are several shortcomings, causing probability assessments to be rather unreliable. Moreover, the analyst must resort to expert opinions for the assessment of failure probabilities. This paper presents an overview of the main topics that were identified in an introductory literature survey and of the key questions which are currently addressed in application-oriented research on this subject. (Edited author abstract) 28 refs.

Van Steen, Jacques F.J. (TNO, Apeldoorn, Neth). *Eur J Oper Res* v 32 n 2 Nov 1987 p 225-230.

**090382 ASSESSMENT OF RISK AT SUPERFUND**

**SITES.** There is general agreement in the risk assessment community on the broad categories of activities to be performed (i.e., exposure, hazard, and risk assessment), but the method of analysis for each element within an activity is presently not uniformly established. The objective of this paper is to describe judgmental decisions that must be made by the risk assessors during the design and execution of a Superfund site assessment, with a focus on the issues of uncertainty and exposure scenarios. The assessment at Western Processing, Washington, is used as an example of the substantial expert judgment required in choosing the analytical methods and appropriate assumptions. (Edited author abstract) 9 refs.

Lincoln, David (CH2M Hill, Bellevue, WA, USA). *Environ Prog* v 6 n 4 Nov 1987 p 212-216.

**090383 MANAGING HAZARDOUS WASTE RISKS UNDER THE MASSACHUSETTS 'SUPERFUND' LAW.** Different options and strategies for managing hazardous waste risks are presented. Experience in Massachusetts under a state 'Superfund' law (Chapter 21E) as applied to the selling, buying, and financing of real estate is drawn upon. The approach discussed is that with a thorough site assessment involving historical research and if required, soil and ground water examination, the parties (sellers, buyers, and lenders) through use of a variety of special devices may successfully consummate real estate transactions. These devices include use of indemnification agreements, escrow funds, title insurance, and in some cases involve accomplishment of tank and contaminated soil removal before closing the real estate transaction. (Edited author abstract)

Paulsen, Frederick S. (Greenman, Grossman & Duffy, Boston, MA, USA). *Environ Prog* v 6 n 4 Nov 1987 p 236-239.

**090384 RISK FACTOR: ACCEPTANCE AND ACCEPTABILITY.** Any assessment of the risks potentially arising from nuclear installations will always be expressed in probabilistic terms, and decisions on a level of risk that can be accepted must therefore involve an element of judgment. Public acceptance of such decisions will depend on the trust that people are willing to place in the industry and in the regulatory authorities. The procedures by which decisions are taken must be seen to be both open and competent. Procedures will have to be targeted towards achieving the necessary high level of trust and credibility. (Author abstract) 41 refs.

Roberts, L.E.J. (Univ of East Anglia). *Nucl Energy* v 26 n 6 Dec 1987 p 349-359.

**090385 PROJECTIONS OF CANCER RISKS ATTRIBUTABLE TO FUTURE EXPOSURE TO ASBESTOS.** To assess the maximum possible impact of further government regulation of asbestos exposure, projects were made of the use of asbestos in nine product categories for the years 1985-2000. A life table risk assessment model was then developed to estimate the excess cases of cancer and lost person-years of life likely to occur among those occupationally and nonoccupationally exposed to the nine asbestos product categories manufactured in 1985-2000. These estimates were made under the assumption the government regulation remains at its 1985 level. Use of asbestos in the nine product categories was predicted to decline in all cases except for friction products. The risk assessment results show that, although the cancer risks from future exposure to asbestos are significantly less than those from past exposures, in the absence of more stringent regulations, a health risk remains. (Author abstract) 26 refs.

Mauskopf, Josephine A. (Research Triangle Inst, Research Triangle Park, NC, USA). *Risk Anal* v 7 n 4 Dec 1987 p 477-486.

**090386 USE OF RISK ASSESSMENT METHODS IN THE CERTIFICATION OF DECONTAMINATED BUILDINGS.** Accidental events such as fires, explosions, and leaks often result in large-scale contaminations of

buildings with toxic chemicals. After decontamination, the certification for original use requires testing for residual contamination. The two basic kinds of sampling plans in use up to recently both fall short of the required performance. Their deficiencies are analyzed in terms of the scientific questions implicit in both the sampling plan and the subsequent statistical evaluation. A sampling strategy of a new kind is proposed and discussed in the same context. It is motivated by concern for the long-term safety of the building's occupants and is, therefore, based on factors important in risk assessment. Three different sampling plans are derived in the framework of this methodology, two of which have already been used in actual certification proceedings. (Author abstract) 18 refs.

**090387 PROBABILISTIC RISK ASSESSMENT: A LOOK AT THE ROLE OF ARTIFICIAL INTELLIGENCE.** A review of traditional Probabilistic Risk Assessment (PRA) methods used in the nuclear power industry is presented. The shortcomings of the current PRA methods are pointed out. A method of performing a PRA is proposed and is computerized. The role of artificial intelligence in developing and performing the proposed PRA approach is discussed. The proposed PRA approach is verified by comparing the results to previously performed PRAs. The comparisons have supported the adequacy and completeness of results of the proposed model. A discussion of how the proposed method can be used as an expert system to verify plant status following loss of plant hardware is also presented. (Author abstract) 36 refs.

**090388 ENGINEERING RISK AND HAZARD ASSESSMENT.** This publication contains 13 papers. These papers deal with issues such as short- and long-term hazards, setting priorities in safety, fault analysis for process plants, hazard identification and safety assessment of human-robot systems, plant fault diagnosis expert systems, knowledge based diagnostic systems, fault tree analysis, modeling of computer security systems for risk and reliability analysis, risk analysis of fatigue failure, fault evaluation of complex system, probabilistic risk analysis, and expert systems for fault detection. All papers are separately indexed and abstracted.

Anon. *Eng Risk and Hazard Assessment* 2 v 1988.

**090389 FAULT TREE ANALYSIS FOR PROCESS PLANTS.** In striving for the improvement of the safety of technical systems numerous formalized procedures for plant safety analysis have been developed. Most of the methods such as Failure Mode and Effects Analysis (FMEA) or Hazard and Operability studies (HAZOP) are qualitative and normally used on their own. They may be applied, however, in preparation of a fault tree analysis, a method usually employed for calculating the probability or expected frequency of an undesired event in a technical system. Safety is the concern, in the case of process plants, as this event may be an explosion, a fire, or a toxic release. In this paper, the concern is with fault tree analysis and its application to process plant safety. Undesired and initiating events in industrial plants are identified using a computer aided search. A case study is presented for a fault tree analysis of a process plant fabricating hexogen. 42 refs.

Hauptmanns, Ulrich (Gesellschaft fuer Reaktorsicherheit, Cologne, West Ger). *Eng Risk and Hazard Assessment* v 1 p 21-60.

**090390 MODULARIZATION METHODS FOR EVALUATING FAULT TREES OF COMPLEX TECHNICAL SYSTEMS.** Fault tree analysis is one of the most important techniques for system modeling and has been widely used in risk assessments together with

event tree models. A fault tree is a graphic representation of the logical relationships between events in a system which result in a prespecified undesired state of it, defined as the top-event of the fault tree. The basic concepts for the deductive elaboration of a fault tree from a top-event are presented. The most frequently used analytical methods for fault tree analysis are based on the determination of the minimal cut sets (MCSs). These are the smallest conjunctions of basic events that lead to the top-event, and are independent from the failure data. The examination of the MCSs provides information about failure modes and weak points of the system and can possibly suggest ways by which the system could be improved. This article proposes a general module concept which allows for an efficient modularization, and gives a method for selecting and evaluating them. The evaluation algorithm presented here is only valid for coherent systems. 19 refs.

Yllera, Javier (Technical Univ, Berlin, West Ger). *Eng Risk and Hazard Assessment* v 2 p 81-99.

**090391 RISK ASSESSMENT - BLACK ART OR SCIENCE?** Risk may be defined as a compound measure of the probability and magnitude of an adverse effect occurring as the result of some activity, and therefore it can be expressed in many different ways depending on its application, e.g. number of lives lost per year, frequency of chromosomal damage etc. It covers all aspects of life and in most cases can either be avoided or its effects reduced in some way or another. In order to achieve reduced risk, however, the possibilities of an 'accident' occurring must be assessed and relevant safety procedures developed. This process of assessment and safety development is known as 'risk assessment'. Measures of risk are discussed. 8 refs.

Moore, Glenis. *IEE Rev* v 34 n 4 Apr 21 1988 p 151-153.

**090392 RISKIEN MINIMOINTI SUUNNITTELUVAIHESSA.** [Minimizing Risks at the Engineering Stage]. The article focuses on hazards leading to property damage and interruption of production in the chemical industry, with a look as well at personal safety and the environment. The author's suggestions for the elimination and reduction of risks at the engineering stage are based on an analysis of major recent losses and on international loss statistics. Distinctive features and applications of the most common methods of risk analysis are reviewed. The status of quantitative risk analyses for chemical processes is examined, and reliability of models used to estimate the magnitude of potential losses is discussed. (Author abstract) In Finnish.

Nygaras, Yngve. *Kem Kem* v 15 n 4 1988 p 362-365.

**090393 RISIKOANALYSE VON DER PLANUNG BIS ZUM BETRIEB.** [Risk Analysis from Planning to Operation]. The most effective and economical method of avoiding loss is to carry out a risk analysis in the planning stage. This analysis consists of risk recognition, risk assessment and risk limitation. The material, liability and personal risks arising during operation are usually dealt with by three measures - reduction (preventive measures), transfer (insurance) and by the concern carrying the risks themselves. Because of its importance to the economic operation of the installation, risk analysis represents a central management task and is a constituent part of the general policy of the undertaking. (Author abstract). 7 Refs. In German.

Franck, E. *Maschinenschaden* v 61 n 3 1988 p 97-102.

**090394 SEISMIC HAZARD PREDICTION USING A PROBABILISTIC-FUZZY APPROACH.** This paper presents a description for extending seismic hazard prediction concepts from probability theory to fuzzy set theory. The aim is to develop a model for seismic hazard prediction able to reproduce both the randomness and the imprecision in conjunction with earthquake occurrences. A particular emphasis is placed upon the treatment of information within a probabilistic-fuzzy mathematical model using the extension principle. (Author abstract). 15 Refs.

USA); Ikejima, Kenji; Hong, Kappyo. *Struct Saf* v 5 n 2 Jun 1988 p 109-117.

**090395 A FORTRAN PROGRAM FOR MULTIVARIATE SURVIVAL ANALYSIS ON THE PERSONAL COMPUTER.** In this paper a FORTRAN program is presented for multivariate survival or life table regression analysis in a competing risks' situation. The relevant failure rate (for example, a particular disease or mortality rate) is modelled as a log-linear function of a vector of (possibly time-dependent) explanatory variables. The explanatory variables may also include the variable time itself, which is useful for parameterizing piecewise exponential time-to-failure distributions in a Gompertz-like or Weibull-like way as a more efficient alternative to Cox's proportional hazards model. Maximum likelihood estimates of the coefficients of the log-linear relationship are obtained from the iterative Newton-Raphson method. The program runs on a personal computer under DOS; running time is quite acceptable, even for large samples. (Author abstract). 7 refs.

Mulder, Paul G.H. (Erasmus Univ, Rotterdam, Neth). *Comput Methods Prog Biomed* v 27 n 2 Sep-Oct 1988 p 175-188.

**090396 SOURCES OF AND EFFECTS OF INTEREXPERT CORRELATION: AN EMPIRICAL STUDY.** Expert estimates are relied on as sources of data whenever experimental data are lacking, such as in risk analysis. Correlation between experts poses problems in the aggregation of multiple estimates. The sources and structure of interexpert correlation are identified, and some of the ramifications are discussed. Expert estimates were found to correlate to the experts' problem-solving techniques and not to any features of their professional backgrounds. The paths that experts used to reach solutions included algorithms and assumptions. Both assumptions and algorithms were found to correlate to the answers because they are integral parts of the path. In addition, correctness of assumptions was found to correlate to the accuracy of the answers. 22 refs.

Booker, Jane M. (Los Alamos Natl Lab, NM, USA); Meyer, Mary A. *IEEE Trans Syst Man Cybern* v 18 n 1 1988 p 135-142.

**090397 RISK ASSESSMENT OF MIXED-WASTE SITES.** Techniques for assessing worker and public risks attributable to atmospherically-released contaminants from a mixed-waste site are presented. The techniques are used to assess, for several different remedial actions, the risk to workers and the public from nonradiative chemicals atmospherically released from several waste sites. Other models and health risk procedures can be used to assess radioactive releases and other applicable environmental media, i.e., surface and ground water. The risks from nonradioactive contaminants that were calculated from the atmospheric pathway are low, no site or site remediation option, taken individually or summed, posed an unacceptable risk to the public. Risks to workers were also well below thresholds accepted by society. 6 refs.

Montague, David F. (JBF Associates Inc, Knoxville, TN, USA); Holton, Gregory A. *IEEE Trans Reliab* v 37 n 2 Jun 1988 p 178-191.

**090398 RISK EVALUATION SYSTEM FOR FACILITY SAFEGUARDS AND SECURITY PLANNING.** The Risk Evaluation System (RES) is an integrated approach to determining safeguards and security effectiveness and risk. RES combines the planning and technical analysis into a format that promotes an orderly development of protection strategies, planning assumptions, facility targets, vulnerability and risk determination, enhancement planning, and implementation. In addition, the RES computer database program enhances the capability of the analyst to perform a risk evaluation of the facility. The computer database is menu driven using data input screens and contains an algorithm for determining

the probability of adversary defeat and risk. Also, base case and adjusted risk data records can be maintained and accessed easily. (Author abstract)

### Computer Aided Analysis

**090400 SCIENTIFIC KNOWLEDGE ACQUISITION DURING THE EXTENSION OF GSA: AN EXPERT SYSTEM FOR GENERIC SAFETY ANALYSIS.** Generic safety analysis (GSA) is implemented on the EMYCIN expert system shell, consists of approximately 150 safety related rules, and runs on a VAX 11-750 computer. To extend GSA, a specialized empirical knowledge base was developed that described the available slip resistance found for various combinations of surfaces, shoes, and contaminants. We chose to directly collect data during a large controlled experiment. The collected data was initially organized by applying statistical methods. After the statistical results were classified into conceptually meaningful categories, a set of rules was easily described and added to the system. The conclusion was that GSA describes an extendable framework that can organize and selectively apply very specialized safety ergonomics research. (Edited author abstract) 26 refs.

Lehto, Mark R. (Purdue Univ, West Lafayette, IN, USA); Miller, James M. *Int J Ind Ergon* v 2 n 1 Nov 1987 p 61-75.

**090401 DEMOS: A COMPUTER AID FOR ENGINEERING - ECONOMIC POLICY MODELING AND UNCERTAINTY ANALYSIS.** A non-procedural environment for engineering-economic policy modeling and uncertainty analysis (called Demos) and an advanced graphic interface to this system (called Demaps) are described. A variety of experimental studies, which critically evaluated these systems, are discussed. These studies demonstrate the importance of adopting an empirical approach to the evaluation of computer systems for decision support and policy analysis and emphasize the limits to which powerful computer aids can be a substitute for knowledge and careful thought. Properly designed, such systems make it easy to examine, exercise, modify and critique, the models they support. This should make it possible to expose these models to more thorough critical peer review, which, over this, could revolutionize the field of quantitative policy analysis. ### Computer Applications

**090402 SENSITIVITY AND UNCERTAINTY STUDIES OF THE CRAC2 COMPUTER CODE.** We have studied the sensitivity of health impacts from nuclear reactor accidents, as predicted by the CRAC2 computer code, to the following sources of uncertainty: (1) the

model for plume rise, (2) the model for wet deposition, (3) the meteorological bin-sampling procedure for selecting weather sequences with rain, (4) the dose conversion factors for inhalation as affected by uncertainties in the particle size of the carrier aerosol and the clearance rates of radionuclides from the respiratory tract, (5) the weathering half-time for external ground-surface exposure, and (6) the transfer coefficients for terrestrial foodchain pathways. Predicted health impacts usually showed little sensitivity to use of an alternative plume-rise model or a modified rain-bin structure in bin-sampling. Health impacts often were quite sensitive to use of an alternative wet-deposition model in single-trial runs. Uncertainties in the inhalation dose conversion factors have important effects on early injuries in single-trial runs. (Edited author abstract) 33 refs.

### Costs

**090403 COST-EFFECTIVENESS OF RISK-REDUCTION MEASURES FROM A NATIONAL VIEWPOINT: A CASE STUDY OF THE ANGRA NUCLEAR PLANT IN BRAZIL.** In this paper a systemic or national approach to cost-effectiveness analysis of risk-reduction measures is reviewed, and its advantages and limitations are discussed. The method is applied to the problem of the cost-effectiveness of increasing the Angra 3 NPP containment wall thickness from the present 60 cm to 180 cm thick in order to prevent damage to the reactor core in case of a direct commercial aircraft crash on it. It is concluded that this measure is not cost-effective if the referred approach is considered. (Author abstract) 24 refs.

### Evaluation

**090404 APPLICATION OF A HAZARD AND OPERABILITY STUDY TO HAZARD EVALUATION OF AN ABSORPTION HEAT PUMP.** A hazard evaluation for a double-effect, absorption heat pumps is presented. The primary technique for the hazard evaluation was a hazard and operability (HAZOP) study; this is a brainstorming approach conducted by a multidisciplinary team. The approach stimulates creativity of the team members to generate ideas. The team consisted of a HAZOP leader, the heat-pump project manager, a thermohydrologist, a corrosion specialist, a toxicologist, and a risk analyst. The majority of the team members were already involved in the design and analysis of heat pump. 2 refs.

**090405 THYROID CANCER RISK FROM EXPOSURE TO IONIZING RADIATION: A CASE STUDY IN THE COMPARATIVE POTENCY MODEL.** Considerable controversy exists about the relative risk of thyroid cancer following exposure to external radiation compared to the risk after exposure to internally deposited <sup>131</sup>I. The human epidemiological data are equivocal, and studies are not directly comparable owing to differing ages at exposure, dose ranges, and periods of follow-up. Limited experimental data at low dose ranges support the hypothesis of equal potency in animals. This report utilizes a relative potency model to reconcile data from

different sources, and to provide an estimate of thyroid cancer risk following human exposure to <sup>131</sup>I. We utilize data from epidemiological studies of external radiation and <sup>131</sup>I exposure in humans and data from an experimental animal study. This analysis shows that the data provide no compelling evidence to suggest that the risks accompanying external radiation or <sup>131</sup>I exposure are different. (Author abstract) 33 refs.

**090406 INFANT EXPOSURE ASSESSMENT FOR BREAST MILK DIOXINS AND FURANS DERIVED FROM WASTE INCINERATION EMISSIONS.** A formula is presented for calculating the infant daily dose of dioxin equivalents from breast milk on the basis of the maternal daily intake. Application of the formula suggests that an infant breast-fed for 12 months would receive around 10% of the cumulative exposure dose per body weight that would be received by an adult with 50 years of exposure, and that the contribution of dioxin equivalent from breast milk to an infant's body concentration would amount to 1.7 times the concentration in the mother. However, dioxin and furan emissions from a source calculated to result in worst-case lifetime cancer risks of the order of 1 in 100,000 are only likely to increase breast milk concentrations by around 1%-10% of the levels that have been detected in several countries. This finding suggests that there are major sources of dioxins and furans other than from municipal solid waste incineration that need to be identified. (Edited author abstract) 17 refs.

Smith, Allan H. (Univ of California, Berkeley, CA, USA). *Risk Anal* v 7 n 3 Sep 1987 p 347-353.

**090407 RESULTS FROM THE TOTAL EXPOSURE ASSESSMENT METHODOLOGY (TEAM) STUDY IN SELECTED COMMUNITIES IN NORTHERN AND SOUTHERN CALIFORNIA.** Volatile organic compound levels (VOCs) in breath, personal air, fixed outdoor air and drinking water samples were measured and compared for a probability sample of individuals in Los Angeles and Antioch/Pittsburg, California, during 1984. In addition, comparisons were made between seasons (winter vs spring) in Los Angeles for individuals sampled in both seasons. For most comparisons, 13 VOC levels were examined for breath, personal and outdoor air samples and four VOCs for water samples. In addition to the results for VOC levels, the paper also briefly describes (i) the sampling procedures used to obtain the study participants, (ii) the collection of air, breath and water samples, and (iii) selected results from the quality assurance procedures used in this study. (Edited author abstract) 10 refs.

Hartwell, T.D. (Research Triangle Inst, Research Triangle Park, NC, USA); Pellizzari, E.D.; Perritt, R.L.; Whitmore, R.W.; Zelon, H.S.; Sheldon, L.S.; Sparacino, C.M.; Wallace, L. *Atmos Environ* v 21 n 9 1987 p 1995-2004.

**090408 CANCER DOSE-RESPONSE EXTRAPOLATIONS.** New dose-response modeling techniques can incorporate representations of the exposure in terms of dose scales based on cell turnover rates, repair processes, immune system responses, and physiological and pharmacokinetic models of absorption, delivery, metabolism, and elimination of chemicals. These new techniques can incorporate distributions of individual background exposure levels and individual susceptibilities to low levels of a chemical. They also can incorporate such factors as low-dose linearity on a biologically relevant scale, and others. This article discusses the subject in terms of relevant dose scales, individual susceptibilities, modeling through time, and related topics. 8 refs.

Sielken, Robert L. Jr. (Sielken Inc, Bryan, TX, USA). *Environ Sci Technol* v 21 n 11 Nov 1987 p 1033-1039.

**090409 EXPOSURE ASSESSMENT.** Exposure assessment is an explicit and central component of the

quantitative risk assessment procedures that are routinely used to formulate chemical regulatory decisions. In its purest form, an exposure assessment identifies all individuals or population subgroups that have been exposed to a chemical and assembles sufficient analytical chemistry data to allow quantitative calculation of the actual doses received by the exposed individuals or populations. The problems of assembling data to achieve quantitative descriptions of exposure cross many disciplinary boundaries. This article discusses the role and practice of exposure assessment, exposure modeling, and other aspects of the subject. 24 refs.

**090410 METHODOLOGY FOR THE SELECTION OF ENVIRONMENTAL DISPERSION MODELS IN HEALTH RISK ASSESSMENTS.** Criteria for the selection of environmental dispersion models in health risk assessments are analyzed. The state of knowledge on the health effect exerts a dominant influence on this evaluation, which focuses on averaging procedures, the resolution in space and time, and error propagation. Uncertainties in the cause-effect relationship are the final contributions to the error of the result. Intermediate calculations should neither increase this error unduly nor be carried out with an accuracy significantly better than that which can be achieved in estimating the health effects. In this context, a methodology for performing credible calculations with an effort commensurate with the state of knowledge is discussed. (Author abstract) 21 refs.

## Management

**090411 KNOWLEDGE-BASED SYSTEMS AND FUZZY SETS IN RISK MANAGEMENT.** An integrated microcomputer-based knowledge system is developed for risk management in construction. The system (Expert-Risk) applies the concepts of fuzzy set theory to evaluate the overall risk of a project. It is also integrated with various relational data bases that provide the system with financial and cost data necessary for bankruptcy and risk analysis. Today's construction industry involves more dynamic and uncertain planning than ever before. Without professional risk management, decision makers cannot systematically approach complex problems. The system provides a more definitive perception of the overall risk of a construction project, and a more rational basis for contingency planning and evaluation. The system allows management to focus on those risk factors which have significant impact on planning. (Author abstract) 20 refs.

**Mathematical Models** See Also CARCINOGENS—Health Hazards; WATER SUPPLY—Planning.

**090412 UTILIZING PROBABILISTIC RISK ANALYSES (PRAS) IN DECISION SUPPORT SYSTEMS.** One of the most useful applications of probabilistic risk analysis (PRA) is to use the PRA to identify the risk importances of design features, plant operations, and other factors that can affect risk. Risk importance as it is commonly used in PRA terminology, is generally the impact on risk that a factor has. The definition and concept of risk importance will be discussed. The risk importance focused upon are those which are derived from the logic structure of the PRA. The logic structure of the PRA includes the fault tree and event tree models, the failure combinations causing undesired events (the minimal cut sets), and the success paths preventing undesired events (the minimal path sets). The structural and logical information in a PRA provides valuable criteria by which to evaluate importances of risk contributors and changes. 4 refs.

## Military Purposes

**090413 RISK ANALYSIS METHODOLOGIES DEVELOPED FOR THE US DEPARTMENT OF DEFENSE.** This paper summarizes a number of quantitative activities which were sponsored by the US Department of Defense in attempts to minimize or control risks associated with military facilities or military testing. A definition of risk and risk management is presented first. This is followed by discussions of: (1) explosive safety risk management including the effects of blast and debris; (2) risk management applied to testing of missiles at national ranges; and (3) risk management associated with minimizing risks due to fire and natural hazards (wind, flood and earthquake) at military facilities. The discussions summarize both the models to compute risk and the methods used to help the decision maker select the conditions which minimize risk within his operating constraints. (Author abstract) 17 refs.

**090414 EVALUATION OF THE VALIDITY OF FOUR HAZARD IDENTIFICATION METHODS WITH EVENT DESCRIPTIONS.** The aim of the investigation was to develop a new method for evaluating the validity of safety analyses with incident and accident descriptions, and to use the approach on some common methods of safety analysis. For this purpose descriptions of disturbances and accidents were collected at seven Finnish process plants. This resulted in 51 incident descriptions. Complementary material (18 incidents) was collected from the FACT data bank. The evaluation concerned four methods - hazard and operability study (HAZOP), action error analysis (AEA), failure mode and effect analysis (FMEA), and management oversight and risk tree (MORT). The basic idea of the evaluations was to use the descriptions of accidents and disturbances as indicators of the real accident contributors, and to decide which of them would have been identified if the methods had been applied in a plant-wide analysis. The results show a total validity of 0.55 of the methods in the cases used in the evaluations.

**090415 NOW OR LATER? A NUMERICAL COMPARISON OF SHORT- AND LONG-TERM HAZARDS.** The author previously presented one of the first papers on the use of numerical methods for comparing the different risks to which employees in the process industries are exposed. Since then such methods have been used for setting priorities between different acute risks and the literature on the subject is now extensive. This paper suggests an extension of these methods to hazards which take a long time, typically several decades, to produce their effects. Consider a substance X, the product of an industrial process, which can cause harm in two distinct ways: (1) it may leak out of the plant, vaporize, mix with air, and be ignited, thus injuring or killing people by fire or explosion. (2) exposure of employees to small quantities of the vapor for long periods for many years may cause industrial disease which may lead to premature death. Usually different people, using different criteria and financed by different budgets are responsible for dealing with two hazards. Finding a way to talk to them both at the same time is like finding a way of communicating at the same time to people who speak different languages. This is attempted in this paper. 34 refs.

**090416 PROBABILISTIC RELIABILITY ANALYSIS, QUANTITATIVE SAFETY GOALS, AND NUCLEAR LICENSING IN THE UNITED KINGDOM.** Although unpublished, the use of quantitative safety goals and probabilistic reliability analysis for licensing nuclear reactors has become a reality in the United Kingdom. This conclusion results from an examination of the process leading to the licensing of the Sizewell B PWR in England. The licensing process for this reactor has substantial implications for nuclear safety standards in Britain, and is examined in the context of the growing trend towards quantitative safety goals in the United States. (Author abstract) 23 refs.

Cannell, William (Commission of the European Communities Joint Research Cent, Ispra, Italy). *Risk Anal* v 7 n 3 Sep 1987 p 311-319.

**090417 ON WEIGHING GAINS AND INVESTMENTS AT THE MARGIN OF RISK REGULATION.** Analysts have long noted an apparent discrepancy in the level of investment seemingly necessary to meet 'acceptable' levels of public safety. At the margin of risk regulation, i.e., where safety determination is judged acceptable, the traditional cost-benefit calculus appears to contribute obvious rationale to the final political decision. Efforts are now being made to introduce a measure of consistency into the application of risk-cost benefit analysis to radiological protection. This paper reviews these efforts from a UK perspective. It also looks at how the issue was treated in a public setting through the Sizewell B Public Inquiry. (Author abstract) 27 refs.

O'Riordan, Timothy (Univ of East Anglia, Norwich, Engl); Kemp, Ray; Purdue, H. Michael. *Risk Anal* v 7 n 3 Sep 1987 p 361-369.

**090418 RISK-BASED ANALYSIS OF EXTREME EVENTS.** Mathematical expectation has traditionally been used in solving risk-based decisionmaking problems. However, this concept is not appropriate for decisionmaking that affects public policy because it conceals extremes by commensurating events of different magnitudes and probabilities of occurrence. A theory relating conditional expectation to the statistics of extremes is developed in this paper. This expectation can now be viewed as the conditional expected risk given the occurrence of an event with a return period that equals or exceeds n years. The theory highlights the importance of using both the conditional and the unconditional expected risk in decisionmaking. This fact has previously been recognized in the partitioned multiobjective risk method (PMRM), a risk analysis methodology based on the concept of conditional expectation. The theory proposed in this paper provides a formulation for analyzing the sensitivity of subjectively chosen parameters in the PMRM. (Edited author abstract) 15 refs.

**090419 DEVELOPING A RISK/COST FRAMEWORK FOR ROUTING TRUCK MOVEMENTS OF HAZARDOUS MATERIALS.** As the United States continues to increase its dependence on industrial technologies which require hazardous materials and generate hazardous wastes, concern is mounting over the safe transport of hazardous cargo. It is estimated that 1.5 billion tons of hazardous cargo are moved through the nation's transportation systems (excluding pipeline), with

truck as the primary mode of transport. Because of the dynamic nature of exposure to the population and environment associated with the transport of hazardous cargo, it is important to develop an accurate representation of this type of transport risk, and to structure a framework for designating a permanent set of shipping routes based on optimizing across risks and costs. This paper describes a methodology which has been developed that incorporates risk and cost into a framework for optimizing the routing of truck movements of hazardous materials. Considerable attention is focused on the risk estimation part of this process, as this is a subject of much uncertainty and of considerable significance to policymakers. The resulting methodology is applied in a regional setting to illustrate its use as an analysis tool. Enhancements to the model structure and extensions beyond the truck routing problem are also discussed. (Author abstract) 19 refs.

Abkowitz, Mark (Rensselaer Polytechnic Inst, Troy, NY, USA); Cheng, Paul Der-Ming. *Accid Anal Prev* v 20 n 1 Feb 1988 p 39-51.

**090420 SETTING PRIORITIES IN SAFETY.** The author believes that not everything possible can be done to prevent every conceivable risk to life, however unlikely or trivial. Sufficient resources are never available. The decisions to be made are these: which risks to remove or reduce first, and which to leave until later, perhaps indefinitely. In other words, we have to set priorities. If a more systematic and more defensible method is found, then there are two distinct approaches: remove or reduce first those risks which exceed a particular level or remove or reduce first those risks that are cheapest to remove or reduce. This paper describes and compares the two methods with particular reference to the process industries, though much of what will be said is relevant to other industries. 28 refs.

Kletz, Trevor A. (Loughborough Univ of Technology, Engl). *Eng Risk and Hazard Assessment* v 1 p 11-19.

**090421 DETERMINING AN ACCEPTABLE LEVEL OF RISK.** A de manifestis level is a ceiling above which events are inherently unsafe and should be regulated without regard for cost. The authors recommend that a population-based de manifestis level be adopted to establish the level above which cancer risks should be considered inherently unsafe and regulated - no matter what the cost. 10 Refs.

Travis, Curtis C. (Oak Ridge Natl Lab, Oak Ridge, TN, USA); Hattemer-Fey, Holly A. *Environ Sci Technol* v 22 n 8 Aug 1988 p 873-876.

**090422 COMPARATIVE PERSPECTIVE OF RISK MANAGEMENT IN THE UNITED STATES AND JAPAN.** A comparative analysis of risk management approaches in the United States and Japan is presented. It is shown there are important differences between the two countries in the approaches and the sources utilized to manage risks. The Japanese approach, which uses administrative guidance, informal persuasion, and education in its governance activities, is contrasted with the more open and adversarial policy-making process in the United States. These general characteristics of governance carry squarely over into each country's characteristic risk-management processes. Four case studies are presented. 12 refs.

## Theory

**090423 THEORY OF POSSIBILITY AND FUZZY SETS.** This report begins with a review of traditional methods of risk analysis the application of risk analysis in the construction industry and discussion of the special conditions in that industry. Then a brief introduction to the theory of fuzzy sets is presented. Special properties are described which characterize methods based on fuzzy sets.

Another theory which is based on the theory of fuzzy sets is possibility theory. The difference between fuzzy sets and possibilities is that possibilities can be used in conjunction with uncertain outcomes, while fuzzy sets are sets with fuzzy boundaries. This means that possibility theory may be regarded as an alternative to probability theory. The principal object of this report is to present three new methods of risk analysis and decision making. The three new methods which have been developed by the author (Indication of risk, Fuzzy ranking and Merging of subjective opinions) are presented both theoretically and by means of examples. 29 Refs.

**090424 DUNAI VIZLEPCSO RENDSZER FOL-DRENGESSEL SZEMBENI ALLEKONYISAGA.** [Stability of the Danube Barrage System Against Earthquakes]. After some information about the origin of earthquakes and about classification according to their nature, some theoretical statements are presented by the author followed by a listing of the earthquakes in Hungary. These events were all attached to three rather characteristic and dangerous break-lines. In case of the Czechoslovak-Hungarian Danube Barrage System, experts of the two countries outlined the situation for the expected earthquake-occurrences. The stability of these earthworks was investigated by deterministic and stochastic methods. Deterministic investigations were carried out by using the Peterson-relationship. Stochastic methods apply random variables like isoseismic lines and their safety factors. The standard deviations of these safety variables were determined in the levees of the reservoirs and upstream canal. Then the probability of collapsing was calculated by assuming normal and exponential distribution. According to these investigations, the probability of breaking-down of the main structures was less than 5 percent. (Edited author abstract) 15 refs. In Hungarian.

**090425 BI-NATIONAL DEVELOPMENT OF THE COLUMBIA RIVER.** Building large and costly water resources schemes is always a complex problem, usually involving special interest groups, and many technical, financial and other experts. When the projects and their associated benefits are spread across more than one nation, the problems are compounded. The Columbia River Treaty, between Canada and the United States, came into being to address some of these problems, and to allow the development of one of the world's largest hydroelectric power systems. After outlining the history of the Columbia River development, following the signature of the Treaty, the authors review current procedures and note how various problems are overcome. (Author abstract)

Dodge, N. (US Army Corp of Engineers, Portland, OR, USA); Newton, T. *Int Water Power Dam Constr* v 40 n 3 Mar 1988 p 33-35.

## Brazil

**090426 INTEGRATED WATER DEVELOPMENT PROJECT OF GRAVATAI RIVER BASIN, BRAZIL.** The integrated Water Resources Development Project of Gravatai River Basin was prepared by the National Drainage Works Department (DNOS) and the German Agency for Technical Cooperation (GTZ). An attempt was made to use the capacity available in other departments and specialized institutes. The objective is to provide information for the departments involved in water resources management so as to enable them to establish specific terms for each hydrographic basin to complement the Federal, state and municipal laws. The basin problems were considered in this work including all aspects related to water resources development. Conclusions were presented as to flow regulation, flood protection, domestic and industrial wastewater, water supply, irrigation, environ-

mental conservation and navigation. (Edited author abstract) 1 ref.

Aoki, Ricardo (Dep Nacional de Obras de Saneamento, Porto Alegre, Braz). *Water Sci Technol* v 19 n 9 1987, Dev in River Basin Manage, Proc of an IAWPRC Conf, Sao Paulo, Braz, Aug 13-15 1986 p 59-68.

## Burkina Faso, Africa

**090427 BARRAGE DE NIOFILA ET AMENAGEMENT DE LA PLAINE DE DOUNA AU BURKINA FASO (EX-HAUTE-VOLTA).** [Nioufila dam and Douna Plain Development in Burkina Faso]. Although located in the Sahel, Burkina Faso has many medium sized rivers allowing the setup of hydraulic development projects at an acceptable cost. The article describes two of these projects: the Douna Plain Development and, immediately upstream, the Nioufila dam. The latter is an earthen flood regulation structure 3,000 m long, 4.5 m at the crest, with a slope of 2 to 1. The Douna Plain Development, which follows it, includes - during an initial phase - an irrigated perimeter of 600 ha (1500 ha later on) with 35,600 m of canals, 16,000 m of which have a concrete lining, access lanes and a drainage network. (Author abstract) In French.

## Danube River

**090428 NAGYMAROSI VIZLEPCSO ALATTI DUNA-MEDER VIZSGALATA.** [Investigation of the Danube River-Bed Downstream of the Water Power Station of Nagymaros]. Planning of the Hydraulic Barrage System of Bos-Nagymaros was initiated in 1952. A feasibility study was finished up in 1968. During the first phase of planning, the necessary conclusions on the bed-conditions were drawn down on the basis of several surveys performed in 1963. The design discharge was determined as 3000 m<sup>3</sup>/s at the power station of Nagymaros. In order to increase the capacity of the power station, this discharge was planned to be carried by the cross-section just downstream of the power station with a water level that was lowered by 0.80 m compared to the present situation with the condition that the coordinated new backwater curve must join the original curve at Budapest on the same, original level. According to the Author's opinion this desired state of the river-bed has been already attained due to large-scale ongoing industrial excavations along the ominous river-stretch from Nagymaros till Budapest. In other words, there is no need for further voluminous excavations to achieve a more economic operation of the power station. (Edited author abstract) In Hungarian.

## Design

**090429 CONSIDERATION ON THE PROBABILISTIC ESTIMATION OF MAXIMUM HYDROLOGICAL QUANTITIES OCCURRENCE.** It is very important in the river-works design to estimate maximum hydrological quantities occurrence, such as the heavy rainfall and the flood. In this paper, assuming that the annual maximum values follow the log-normal distribution, we consider the distribution of the maximum values which occur within the lifetime of structure for river-works. And analyzing the data from four stations (Kanazawa, Toyama, Fukui and Nanao), we find that the hydrological variable in accordance with large return period is nearly equal to the value which is the mode of the annual maximum values distribution that can occur within the lifetime of the structure. Furthermore we suggest the statistical method to evaluate the occurrence times and magnitude when severe hydrological events occurred repeatedly in a fixed interval. (Author abstract) In Japanese. 8 refs.

## Drainage

**090430 VIZRENDEZES ES FEJLESZTÉSE AZ ALSO-TISZA-VIDEKI VIZUGYI IGAZGATÓSÁG TERÜLETÉN.** [Land-Drainage and its Development in the Area of the Lower-Tisza Valley Regional Water Authority]. The introduction of flood-protection in the Tisza Valley in the last century secured the conditions of a safe agricultural production over one-fifth of the area of Hungary and promoted transportation, traffic, industrial development and the living-conditions of its inhabitants. The continuous system consisting of levees, however, closed off the drainage of logging waters from the protected area in its natural way and created a new problem: called land-drainage. Land-drainage cannot function without dense and well-maintained canal-networks, without a structure-system for water diversion and without pumping-stations, occasionally. A coordinated development and operation of the canals of different order and purpose is a basic task of this technical field. To foster coordinated development, the Lower-Tisza Valley Regional Water Authority had ordered to prepare in 1976-1978 a conceptual plan for land-drainage development in the counties of Csongrad, Bekes and Bacs-Kiskun. Beside constructing the necessary earthworks and structures, the Regional Water Authority was eager to help the accomplishment of the work-phases of complex amelioration especially through the construction of automatically controlled, prefabricated pumping stations and of pipe-drainage systems. (Edited author abstract) 2 refs. In Hungarian.

## India

**090431 CRUCIAL ISSUES IN GEOTECHNICAL ENGINEERING OF WATER RESOURCE PROJECTS.** The difficulties experienced in geotechnical investigations of some river valley projects have been presented. The importance of systematic investigations has been stressed in order to evolve safe and economical design. The experiences from Salal Hydro electric Project, Loktak Hydro electric Project and Srisaillam Hydro electric Project have been described. The need for a specialized cadre in geotechnical engineering devoted to water resource development projects has been stressed. (Author abstract). 13 Refs.

Madhavan, K. (Central Water Commission, New Delhi, India). *Indian Geotech J* v 18 n 1 Jan 1988 p 1-30.

## Legislation

**090432 HYDRO DEVELOPMENT ON INTERNATIONAL RIVERS.** A considerable portion of the world's remaining hydro potential, which is technically and economically exploitable, is on rivers which flow through more than one country. The development of these valuable resources is often delayed while lengthy negotiations between neighbouring countries take place. This article looks at some of the legal, technical, economic and environmental issues which have to be addressed when bi-national schemes are constructed. (Author abstract) 10 refs.

Focsa, V. *Int Water Power Dam Constr* v 40 n 3 Mar 1988 p 38-39.

**Management** See Also WATER RESOURCES—Sudan.

**090433 TARAWERA RIVER MANAGEMENT PLAN.** The pulp and paper industry was established on the banks of Tarawera River in the 1950s. The site was chosen for two principal reasons, the availability of the river both as a source of water and a medium for effluent disposal and the availability of geothermal energy. Concern in the 1980s at the polluted state of the Tarawera River below the industrial discharges, coupled with proposals for expansion of the established industry led to

a requirement for the preparation and adoption of a Management Plan for the river and its catchment. The paper discusses the plan, its preparation and the implications for the pulp and paper industry at Kawerau. (Edited author abstract).

## Mathematical Models

**090435 IRRIGATION PLANNING MODEL FOR DAMODAR-BARAKAR RIVER BASIN.** The Damodar-Barakar river basin is an inter-state basin falling in the states of Bihar and West Bengal. According to an agreement between the governments of Bihar and West Bengal regarding sharing of water in the basin, the share of Bihar is limited to a meagre quantity. Therefore, it is important to utilize the water in a more scientific way to derive the optimum benefit. In the basin, while planning an irrigation project, the areas of crops are fixed arbitrarily on the basis of total 75% dependable inflow. Hence, keeping all these in view, a linear programming model for irrigation planning has been developed considering periodical inflow of 10 days and evaporation losses for the whole year to serve as a guideline for irrigation planning in the Bihar portion of the basin. (Edited author abstract) 7 refs.

## Philippines

**090436 LESSONS FROM EIA FOR BICOL RIVER DEVELOPMENT IN PHILIPPINES.** Beginning in 1975, the Bicol River Basin Development Program (BRBDP) embarked on a plan to develop the Rinconada area by providing integrated projects for rural development. Environmental studies were done, but largely in response to procedural requirements of the U.S. Agency for International Development; the Philippine environmental impact statement requirements were not taken seriously. The resulting environmental assessment was inadequate and failed to predict negative impacts that followed project implementation, particularly construction of the Lake Buhí regulation project. The controversy caused by the adverse effects necessitated follow-on environmental studies and engineering works and enhanced the BRBDP's appreciation of environmental impact assessment as a practical planning tool. (Author abstract). 12 Refs.

## Saskatchewan

**090437 WATER QUALITY DETERIORATION DURING INTERBASIN TRANSFER IN SASKATCHEWAN.** Two existing diversion schemes have been studied over a period of 15 years. These two schemes and one proposed diversion scheme are reviewed with a direct interest in identifying potential and actual causes of water quality deterioration which exists now or may exist in the future. Specifically the diversion schemes are: (1) the Qu'Appelle diversion with water being discharged into the Qu'Appelle River from Lake Diefenbaker for enhancement of drinking water quality for the cities of Regina and Moose Jaw and to provide irrigation water downstream, and (2) the Saskatoon Southeast Water Supply System with water being transferred from Diefenbaker Lake to multi-purpose users in a 120 kilometer long arc south and east of Saskatoon. The quality of the diverted waters in both schemes undergoes rapid and permanent deterioration which results in lower value supplies for irrigation, industrial, and domestic uses. Additional study results are discussed. (Edited author abstract). 7 Refs.

## Taiwan

**090438 WATER CLASSIFICATION IN THE TANSUI RIVER BASIN IN TAIWAN.** This paper is based on a study conducted to assess and classify the Tansui river in Taiwan, taking into consideration several relevant parameters. The classification was performed using a new approach. First, the current general uses of the river were assessed; classification was then made by river area, and the priority uses of each. Second, existing water quality was assessed using an indexing approach, specifically the River Pollution Index (RPI). This takes into account all relevant pollution variables, eg. DO, BOD, coliform count, etc. to determine the level of water quality at different reaches of the river. Finally, a classification of the Tansui river based on its existing water quality and specific best usage was made. (Author abstract). 4 Refs.

## USSR

**090439 AMERICAN SCIENTIST ON INTERBASIN WATER TRANSFER IN THE USSR.** Among the American authors who have already elucidated various aspects of this problem for a comparatively long time is Western Michigan University Professor Ph. Micklin - a prominent specialist in the USA on water resources of the USSR and problems of their territorial redistribution. In his work the American scientist actively uses Soviet official government documents, scientific journals, monographs, etc. An analysis of the Soviet literature and his own scientific studies enabled Micklin on the whole to thoroughly discuss the problem. Certain points of his works of interest also for the Soviet reader are discussed in this paper. 15 refs.

**090440 DISTRIBUTION OF CHEMICALS IN RIVERS DURING CONTAMINATION AND RECOVERY.** Differential equations that describe the fate of chemicals in rivers as they transfer, react, and volatilize, both during contamination and recovery are developed. Explicit analytical solutions are presented for the unsteady distribution of the substance in the aqueous and sediment phases assuming a constant partition coefficient. The solutions are expressed in terms of three parameters, dimensionless distance  $Z$ ; dimensionless time  $T$ ; and the conservation index  $K$ , which equals 1 for conservative nondegrading substances, and zero for infinitely fast loss or degradation. All three parameters are instrumental in defining limits for important asymptotic cases. (Edited author abstract) 14 refs.

**090441 DESIGN AND CONSTRUCTION OF AN ARTIFICIAL CANOE SLALOM COURSE AT HOLME PIERREPONT, NOTTINGHAM.** The artificial canoe slalom course opened by HRH the Princess Anne on 13 September 1986 makes the National Water Sports Centre at Holme Pierrepont one of the most comprehensive and easily accessible centres for canoe sports in the world. Funded by the Sports Council, Nottinghamshire County Council and the British Canoe Union at a cost of £2.2 million, the course is the first purpose-built international standard artificial canoe slalom facility in the UK. The course is three miles downstream of Nottingham on the River Trent and allows part of the river flow to bypass Holme Sluices. The discharge of the course can be varied to modify the difficulty of the water features to suit differing levels of expertise. Extensive use was made of hydraulic models in the design of the course which takes the form of an irregular series of stepped pools connected by horizontal trapezoidal channels. (Author abstract) 6 refs.

**090442 METHOD FOR MANAGING RIVER ABSTRACTIONS AND PROTECTING THE ENVIRONMENT.** An improved method has been developed to assess and control the quantity of water available to river abstractions. The methodology quantifies the sensitivity of the river environment to abstraction by a weighting system, and uses this to establish, on a subcatchment basis, maximum permissible volumes of abstraction and minimum permissible river flows. Guidelines developed from the methodology have been used as the basis for determining applications for abstraction licenses in North Yorkshire, before being extended to cover the rest of the Yorkshire Water area. (Author abstract) Refs.

Drake, P.J. (Yorkshire Water Authority); Sherriff, J.D.F. *J Inst Water Environ Manage* v 1 n 1 Aug 1987 p 27-38.

**090443 DURBAN - TOO MUCH WATER - TOO LITTLE WATER.** The exceptional continuous heavy rain in the catchments of the major Natal rivers flowing through Durban caused very high flood levels to occur. The magnitudes of the floods are considered, as are the means of determination of the flows. The major damage due to the high flows of the rivers, particularly in respect of the Umgeni and Umlaas Rivers, created major problems in maintaining water supply and waste water treatment services in the entire densely populated metropolitan area. The steps taken to deal with these problems are outlined. Also considered are the effects of property flooding, damage to other services and the resultant change in river regimes. (Author abstract)

**090444 CHANNEL CHANGE, FLUVIAL GEOMORPHOLOGY AND RIVER ENGINEERING: THE CASE OF THE AFON TRANNON, MID-WALES.** The Afon Trannon, a gravel-bed river in

mid-Wales with a catchment area of 72 km<sup>2</sup>, has recently been the subject of an engineering flood protection scheme. Geomorphological investigations are described which attempt to pinpoint the lessons of the scheme. Historical studies of floodplain sediments and channel change indicate firstly, an initially rather stable channel, but secondly a considerable, early history of channelization which may still have repercussions for system stability. This early channelization has now been modified in the recent scheme. Contemporary field study by survey and sediment tracing using the magnetic technique indicates the present instability of the sediments in a meandering channel given a trapezoidal cross-section and varied banks. Low-flow adjustments are as important as flood adjustments in the lower, straightened reach. (Edited author abstract) 20 refs.

**Bank Erosion** See Also CANALS; CANALS—Bank Erosion; HYDROELECTRIC POWER PLANTS—Standardization; STREAM FLOW—Mathematical Models.

**090445 RIVERBANK STABILITY ANALYSIS. I: THEORY.** In this paper, a slope stability analysis for steep banks is used in conjunction with a method to calculate lateral erosion distance, to predict bank stability response to lateral erosion or bed degradation. The failure plane angle, failure block width, and volume of failed material per unit channel length may be calculated for the critical case. These parameters define the bank geometry following failure and form the starting point for subsequent analyses. The calculation procedure is illustrated by a worked example. Following mass failure slump, debris accumulates at the bank toe. The debris is removed by lateral erosion prior to further oversteepening or degradation generating further mass failures. Any process-based model for channel width adjustment must account for the combined effects of lateral erosion and mass instability in producing bank instability. (Edited author abstract) 14 refs.

Osman, Akode M. (Univ of Khartoum, Khartoum, Sudan); Thorne, Colin R. *J Hydraul Eng* v 114 n 2 Feb 1988 p 134-150.

**090446 RIVERBANK STABILITY ANALYSIS. II: APPLICATIONS.** Bank retreat occurs by a combination of lateral erosion by the flow and mass failure under gravity. A new analysis of bank erosion and failure is developed, using a critical shear-stress concept to account for lateral erosion and a slope stability criterion for mass failure. In this paper, we apply the analysis to two problems of bank retreat often encountered by practicing engineers dealing with alluvial channels. The first application is to the prediction of degradation downstream of a dam for the case in which bed lowering causes bank instability. The second application is to the modeling of flow in channel bends and the prediction of the equilibrium cross section. (Edited author abstract) 12 refs.

## Bank Protection

**090447 OLD RIVER OVERBANK STRUCTURE, LOUISIANA: HYDRAULIC MODEL INVESTIGATION.** Physical hydraulic model tests were conducted to investigate the hydraulic performance of the stilling basin and evaluate riprap stability and scour potential with the existing overbank structure. Most tests were conducted in a 1:25-scale section model of six bays and one abutment. Other tests were conducted in a 1:44-scale section model and the existing 1:120-scale general model. A variety of operating configurations with alternate bays and panels in each of the six bays were used to determine adequate operating conditions and limits of safe operation for the total 73-bay structure. Tests were conducted for the full range of anticipated operating conditions with consecutive bays fully open and fully closed, and with controlled flow

through each of these timber panel configurations in each bay of the structure. Controlled flow through partially opened bays with staggered timber panels was the most satisfactory manner of operating the overbank structure and, therefore, is the recommended plan. (Edited author abstract)

## Cape Fear River

**090448 CORRELATIONS BETWEEN BASIN DEVELOPMENT PARAMETERS AND WATER-QUALITY CHARACTERISTICS OF THE CAPE FEAR RIVER AT LOCK 1 NEAR KELLY, NORTH CAROLINA.** Water-quality data from long-term (24 years) fixed-station monitoring at the Cape Fear River at Lock 1 near Kelly, N.C., and various measures of basin development are correlated. Subbasin population, number of acres of cropland in the subbasin, number of people employed in manufacturing, and tons of fertilizer applied in the basin are considered as measures of basinwide development activity. Linear correlations show statistically significant positive relations between both population and manufacturing activity and most of the dissolved constituents considered. Negative correlations were found between the acres of harvested cropland and most of the water-quality measures. The amount of fertilizer solid in the subbasin was not statistically related to the water-quality measures considered in this report. For the chemicals evaluated, manufacturing and population sources are more closely associated with water quality in the Cape Fear River at Lock 1 than are agricultural variables. (Edited author abstract) 9 refs.

**Contamination** See Also FLOW OF FLUIDS—Pipes.

**090449 FACTORS AFFECTING METAL PARTITIONING DURING RESUSPENSION OF SEDIMENTS FROM THE DETROIT RIVER.** The release of previously deposited substances from sediments may represent a significant source of contaminants to the overlying water. Of special concern is the partitioning between aqueous- and sediment-phase heavy metals in response to resuspension events induced by hydrodynamic forces. In this paper results from a set of field experiments are reported in which sediment cores from three stations in the Trenton Channel of the Detroit River were artificially resuspended. Statistical analysis of the data indicated that the concentrations of the dissolved metals Cd, Co, Cu, Ni, Pb, and Zn in the overlying water varied inversely with pH ( $p < .05$ ) and directly with time when the pH was below 7.5. These results are interpreted in terms of surface sorption reactions, particle size distributions, and mass transfer controls on metal-sediment reaction rates. (Edited author abstract) 18 refs.

**090450 WATER QUALITY AND DIATOM COMMUNITIES IN TWO CATALAN RIVERS (N.E. SPAIN).** Benthic diatom assemblages have been used to evaluate the water quality of two rivers subjected to marked human influences. These rivers, the Llobregat and the Ter, are located in N.E. Spain, and supply water for

industrial, agricultural and urban requirements of roughly three million people. The diatom communities in the headwaters are similar in both rivers (*Achnanthes minutissima*, *Cymbella ventricosa*, *Gomphonema angustatum*). In the river Ter significant pollution modifies this community and *Nitzschia palea*, *Nitzschia gandersheimiensis* and *Gomphonema parvulum* appear as the most tolerant species. In the Llobregat, the pollution from the salt mine operations also modifies the diatom assemblage. Reservoirs in the river Ter improve the quality of water and a community of *Fragilaria* sp. pl. becomes dominant downstream. (Edited author abstract) 30 refs.

**090451 ZALA VIZGYUJTOJENEK EROZIOS VIZONYAI ES HATASUK A FELSZINI VIZEK MINOSEGERE.** [Erosion in the Catchment of the Zala River]. First, the triggering and influencing factors initiating non-point (areal) erosion were evaluated. Individual factors were afterwards weighted according to characteristic slopes, precipitation and soils (taken as constant or barely unchanged). Based on this information, erosion endangerment or erosion potential of an area were calculated and presented. Modification of applied agrotechnical measures has been recommended with due regard on soil-protection. Changes in land use were also proposed with consideration on the agroecological potential. In practice, the pollution-load of the Zala river was evaluated on the basis of measured sodium-phosphorus-potassium values in the different cross-sections. The values were correlated to the types and amount of the pollutants originated in the particular area. It has become clear that diffusive pollutants (stimulated by soil-degradation) are essential from the point of view of water quality in the tributaries. (Edited author abstract) 18 refs. In Hungarian.

**090452 MESURES DE LA QUALITE DES RIVIERES: STATIONS AUTOMATIQUES.** [Measurement of River Water Quality: Automatic Measuring Stations]. Automatic measuring stations are often used as warning stations to protect drinking intakes; they constitute also significant tools for the study and modeling of natural phenomena and treatment processes. These aspects and various techniques are presented with emphasis on recent achievements. Automatic measuring stations are not yet well developed because of their costs, technological difficulties, personal requirements, and inadequate regulations. The development of this kind of instrumentation will proceed together with an opening of the French designers towards the foreign market and with improved regulation. Moreover, it is necessary to develop new sensors in order to cover a great number of chemical matter while an increase in the number of instruments. (Author abstract) 12 refs. In French.

**090453 LE REGLAGE DES NIVEAUX PAR BARRAGES MOBIILES POUR DES OUVRAGES A FAIBLES RETENUES. LES BARRAGES MOBIILES ADAPTES AUX FAIBLES RETENUES.** [Water Level Regulation in Rivers by Navigation Barrages in the Case of Small Heads]. Taking advantage of the information relating to older navigation barrages, we have looked at the evolution of modern barrages with electro-mechanical command systems. For low heads (3 to 5 m), we suggest to build single element barrages, because of the use of an upper element reduces too much the stiffness of the barrage. Our study develops the concept of a single element barrage, which can be lifted and lowered, and which is applied to a segment gate. We present a draft project for a barrage with 3×30-meter spans and a 5-meter head. (Author abstract) In French, English. 4 refs.

**090454 OLD RIVER CONTROL AUXILIARY STRUCTURE; HYDRAULIC MODEL INVESTIGATION.** Model tests of the Old River Control Auxiliary Structure were conducted to investigate and develop a design that would provide satisfactory flow characteristics in the approach channel, at the abutments, over the spillway, in the stilling basin, and in the exit channel, and determine the adequacy of the riprap protection proposed for the approach and exit channels. The approach channel provided satisfactory flow to the spillway for all anticipated flow conditions. A design for the approach training walls was developed. Spillway discharge characteristics were determined for the following flow conditions: free uncontrolled flow, submerged uncontrolled flow, free controlled flow, and submerged controlled flow. Tests indicated that the downstream portion of the stilling basin training wall could be lowered for a length of 63 ft without impairing hydraulic performance. (Edited author abstract).

**090455 NEW METHOD FOR THE CONTROL OF THE RIVER NILE.** This paper introduces a new stochastic control method, Extended Linear Quadratic Gaussian control, that appears to be particularly promising for the management of complex reservoir configurations such as the River Nile system. The method is introduced by means of a short case study related to the regulation of the Equatorial Lakes in the Nile basin. If the necessary data are available, the method can be easily adapted to the entire Nile system and used to investigate a variety of management issues. (Author abstract). 13 Refs.

**090456 CROSS-CHANNEL MIXING AND ITS EFFECT ON SEDIMENTATION IN THE ORINOCO RIVER.** At high discharge, cross-channel mixing of water in the Orinoco River main stem requires several days and up to 500 km of downriver transit for completion. During mixing, substantial amounts of <0.063 mm sediment are lost from suspension. The water closest to the left bank appears to lose the most, probably by deposition onto the floodplain. This occurs in two ways. First, sediment-laden left-bank tributaries draining the Andes, such as the Apure, deposit sediment in distributary systems following impoundment by the Orinoco backwater. Second, when sediment-laden waters from the Andes actually join the Orinoco, the slow nature of cross-channel mixing causes the water and sediment to be confined more to the left side of the channel. (Edited author abstract) 20 refs.

Stallard, R.F. (Princeton Univ, Princeton, NJ, USA). *Water Resour Res* v 23 n 10 Oct 1987 p 1977-1986.

**090457 EFFECT OF LARGE-SCALE AFFORESTATION ON TARAWERA RIVER FLOWS.** Over 250 km<sup>2</sup> of the Tarawera catchment (906 km<sup>2</sup>) in the central North Island, New Zealand, was planted in pine forest between 1964 and 1981. This change has affected flow of the River Tarawera. Between 1964-81 annual, summer and winter Tarawera flows showed significant reductions of 10.9 m<sup>3</sup>/s, 11.4 m<sup>3</sup>/s and 9.6 m<sup>3</sup>/s respectively. Simple flow models for the Tarawera, and two neighboring catchments that had undergone little landuse change, showed that about 4.5 m<sup>3</sup>/s of these reductions, 13% of the mean flow over the calibration period, could be attributed to afforestation while the remainder was due to

decreased rainfall. The reduction attributed to afforestation was in accord with the results of small catchment studies. (Author abstract) 17 refs.

**090458 SYNTHESIS OF MONTHLY FLOW DURATION CURVES FOR UNGAUGED WATERCOURSES.** Monthly flow duration curves (FDCs) were required to allow economic and financial analyses to be performed for small run-of-river hydro stations, unconnected with a regional electricity grid, where the output was used mainly for crop-processing. This Technical Note describes an empirical method for synthesizing monthly FDCs from limited hydrological data for small-catchment ungauged watercourses. The method involves comparisons on monthly rainfall on a limited number of gaging-station catchments with monthly rainfall on the ungauged catchments, and an assumption that the respective FDCs have the same shape. (Author abstract) 2 refs.

Wilson, E.M. (Univ of Salford, Engl). *Proc Inst Civ Eng (London)* v 83 pt 2 Sep 1987 p 637-641.

**090459 EVALUATION OF THE SLOPE-AREA METHOD FOR COMPUTING PEAK DISCHARGE.** An evaluation of 70 slope-area measurements on higher gradient streams (strength slopes greater than 0.002) throughout the United States showed that peak discharge measurements were affected by n-values, scour, expansion and contraction losses, viscosity, velocity distribution, unsteady flow, number of cross sections, state of flow, and stream slope. In many places, measurement error can be as great as, or can exceed, 100 percent, which leads to over-estimation of the actual peak discharge. This can result in misleading maximum flood values, flood-frequency analyses, and overdesign of flood-plain structures. A brief discussion of these problems, tentative solutions, and research needs is presented. The critical-depth method of computing peak discharge provides the most reasonable results in higher gradient streams. (Author abstract) 38 refs.

Jarrett, Robert D. *Geol Surv Water Supply Pap (US)* 2310 Dec 1986 p 13-24.

**090460 TOTAL LINEAR RESPONSE MODEL (TLR) AND THE LINEAR PERTURBATION MODEL (LPM).** In this paper, two models are introduced for the river forecasting system. One is named TLR, which is based on the assumption that the total rainfall and total discharge are related by a linear and time invariant system. The other one by the name of LPM is suggested for rivers whose seasonal variation is relatively predictable and in this model the series of departures from the normal (seasonal) behavior in rainfall and discharge are related by a linear and time invariant system. To date, these two models have been applied with promising results to a number of large rivers with single (or multiple) input and single output. The application of the TLR and the LPM to the Three Gorges catchment of the Changjiang (Yangtze) River yields successful results. (Author abstract) In Chinese. 5 refs.

Wen, Kang (Nanjing Research Inst of Hydrology & Water Resources, China); Liang, Gengchen. *Shuili Xuebao* n 6 1986 p 1-10.

**090461 DEBITMETRIE: PRECISION DES STATIONS DE JAUGEAGE.** [Discharge Measurements: Gaging Station Accuracy]. Gaging stations data are used in order to establish annual reports of river's discharge. These data are continuous records of water level and intermittent discharge measurements. From them are established stage-discharge curves for a given river. This operation involves many of uncertainties. The ways to fit such curves to the data and to estimate their accuracy in the discharge medium range are explored. The greatest uncertainties arise in the curve's extrema and with the curves fitting according to artificial or natural and

seasonal flow condition changes. Unfrequent gaging may lead to strong temporarily systematic errors. (Author abstract) 13 refs. In French.

**090462 STUDY OF HYDRAULIC BEHAVIORS OF RIVER EFFLUENT AT CORIOLIS FORCE DOMINATING FIELD BY REMOTE SENSING.** River effluents discharged into coastal water zones around the Honshu Islands in Japan are visualized by Landsat data with a view to observe behavior extremely far from river mouths. Landsat data indicate that the effluents in this sea area are affected significantly by oceanic currents such as the Branch of the Tsushima Current in the Sea of Japan and the Kuroshio Current in the Pacific Ocean. In the Sea of Japan, the river effluents at the extremely far field have a tendency to flow north along the coastline. In the Pacific Ocean, large scale eddies, which are formed by interaction between various oceanic current systems, may entrain the coastal water masses in them. (Edited author abstract) 3 refs.

**090463 LONG RANGE STREAMFLOW AND WORLD CONTINENTAL RUNOFF FLUCTUATIONS SINCE THE BEGINNING OF THIS CENTURY.** Fifty major rivers, distributed all around the world, have been selected and since the beginning of this century their mean annual discharge fluctuations have been studied by filtering methods. In the first part of this work, the authors determine what are the great hydroclimatic periods which have affected the different drainage basins. In the second part, the runoff fluctuations of each continent are reconstituted using the discharge fluctuations of some selected and representative rivers. Thus, the world continental runoff fluctuations are calculated by summing the fluctuations of the different continent runoffs. The world continental runoff is greatly influenced by the Asiatic Continent. Furthermore, North American and European runoffs fluctuate in opposition while South American and African runoffs present synchronous fluctuations. Additional aspects of the study are discussed. (Edited author abstract) 45 refs.

**090464 INFLUENCE OF CHANNEL WIDTH ON BED LOAD TRANSPORT CAPACITY.** The influence of channel width on bedload capacity in river reaches of given slope, water discharge, and channel-bed material is examined. The view that transport capacity is a decreasing function of width is shown to be dependent upon an invalid premise. A contrary view - that transport capacity increases as channel width increases - is also considered. Conclusions based on the second view are shown to be inconsistent with transport formulas or are restricted to channels at a near-threshold state. The existence of an optimum width that maximizes capacity is demonstrated. This is a consequence of the nature of the relationship between bedload transport rates and flow intensity (notably a threshold condition) and of the relationship between flow resistance and depth. Expressions are derived for the optimum channel width and are shown to predict Gilbert's flume observations. Problems are considered in applying this approach to natural channels. (Author abstract) 30 refs.

**090465 DISCALC: A COMPUTER ALGORITHM FOR COMPUTING THE FLOW CHARACTERISTICS OF FLOOD DISCHARGES IN STREAM CHANNEL CROSS SECTIONS.** DISCALC is a com-

puter program that calculates uniform-flow characteristics of flood discharges within stream-channel cross sections. It eliminates computational bias by calculating hydraulic measures based on their precise mathematical definitions. The algorithm contains an iterative routine that converges on the desired discharge by changing the vertical position of the water surface within the stream-channel cross section. The program is capable of handling single thread as well as multithread channels. It also contains options for displaying results on a color monitor or a plotter. (Edited author abstract) 17 refs.

**090466 EFFECT OF RUNOFF VARIABILITY ON DEFORMATION OF ERODIBLE CHANNELS NEAR STRUCTURES.** At present a large number of works having a genetic basis are devoted to an analysis of channel transformations near engineering structures. However, as many natural phenomena, the fluvial process has also stochastic properties, and therefore also the stochastic basis should be used along with the genetic in its study. The stochastic component of the fluvial process is determined by the asynchronism of the transient flows of the liquid phase in the river channel and the solid phase in its bottom region. A study of processes of channel deformations from a stochastic standpoint makes it possible to prove that series of morphological characteristics have the property to lose correspondence with the initial hydrological series with respect to probability. Data of on-site observations were analyzed for an experimental confirmation of the foregoing. A bridge across a large river with a readily mobile channel (channel braiding) was selected as the object with complex hydrological and morphological conditions. 4 refs.

**090467 CHANNEL DISCHARGE MEASUREMENT BY THERMODILUTION.** An investigation was conducted to determine the feasibility of applying thermomodulation technology to discharge measurements in small open channels. A series of tests were performed in which the time-temperature dilution curves were recorded and analyzed. The independent variables included the channel discharge, the injectate drop height, the volume of tracer, and the mixing distance. Flows ranged from 0.67 cfs to 2.45 cfs with Froude numbers less than 0.30. The results indicated that the thermomodulation technique is a feasible method for discharge measurement. An empirical expression was derived to determine the approximate mixing distance as a function of the flow depth. (Edited author abstract) 10 refs.

**090468 ERRORS IN SLOPE-AREA COMPUTATIONS OF PEAK DISCHARGES IN MOUNTAIN STREAMS.** During an evaluation of 70 slope-area measurements on higher-gradient streams (stream slopes greater than 0.002) throughout the United States, peak discharge measurements were found to be affected by n values, scour, expansion and contraction losses, viscosity, unsteady flow, number of cross sections, state of flow and stream slope. Problems due to measurement error can often be as great as or greater than 100% and leads to overestimation of the actual peak discharge. This can result in misleading maximum flood values, erroneous flood-frequency analyses and overdesign of flood-plain structures. A brief discussion of these problems, tentative solutions and research needs is presented. The critical-depth method of computing peak discharge provides the most reasonable results in higher-gradient streams. (Author abstract) 30 refs.

**090469 STUDY OF RIVER REAERATION AT**

**DIFFERENT FLOW RATES.** The lower Tarawera River in New Zealand is a fast-flowing, turbulent water body that is used for the disposal of wood-pulp mill wastes. A number of gas tracer measurements are carried out to measure the reaeration coefficient,  $K_2$ , at different flow rates. The magnitudes of the results are best described by energy dissipation models. Such models are better able to describe reaeration in turbulent waters having appreciable surface disruption. Results show that  $K_2$  decreases slightly, but significantly, as flow rate increases and that this trend is better described by a surface renewal model than by energy dissipation models. The trend with flow is incorporated into the energy dissipation model by using nonlinear regression to develop an expression for the escape coefficient that is a function of the flow rate. (Edited author abstract) 30 refs.

**090470 CALCULATING BED LOAD DISCHARGE IN UNSTUDIED RIVERS DURING LOW FLOW PERIOD.** Based on the graphic method of identifying ridges of different orders of magnitude in the structure of the bottom relief, we can determine bed forms which constitute the main form of transport of bed load during the low flow period. The parameters of the bed forms are functions of the size of the rivers, calculated by the arbitrary dichotomy scheme of E.A. Chernykh. With an increase in the size of the stream the height increases and the rate of movement of ridges of a given size decreases. Empirical dependences are obtained for calculating these ridge characteristics. They are the basis for determining the bed load discharge in unstudied segments of rivers. (Author abstract) 6 refs.

**090471 METHOD OF CALCULATING REFORMATIONS OF BRAIDED RIVER BEDS WITH VARIABLE HYDROLOGICAL CONDITIONS.** The method is based on the use of hydrological-morphometric dependences. The magnitude of channel-forming discharge, which is part of them, is calculated by the method of N.I. Makkaveev, which considers the variation of the water regime through the transformation of the discharge frequency curve. The method considers the redistribution of discharge among arms upon a change in their morphometric characteristics. Calculation of the reformation of a segment of the lower course of the Yenisei R. is presented as an example. (Author abstract) 10 refs.

**090472 COMPUTATION OF RIVER FLOW AND BED-LOAD TRANSPORT.** The George Washington University (GWU), Washington, D.C. and the Research Centre for Water Resources (VITUKI), Budapest, undertook a joint research project in cooperation between the U.S. National Science Foundation and the Hungarian Academy of Sciences. This joint research project, 'Computation of River Flow and Bed-load Transport' was conducted in the period 1983 to 1986. This report summarizes the main results of the project. Using a step-by-step method of computation of flow and bed-load transport, a full description of river channel changes becomes feasible, provided no transverse water and sediment flows occur (basically straight channels are assumed). The verification and application of the developed method were performed by using the observed data for the Danube and Raba Rivers in Hungary. 27 refs.

**090474 RIVER FLOW FORECASTING FOR MULTIPLE TIME PERIODS.** The performance of a river flow forecasting model employing a Kalman filtering algorithm was evaluated for increasing forecast lead times. The expected decrease in forecast accuracy was quantified and a decrease in forecast precision was noted for increased lead times. The merits of external estimates of meteorological inputs to the model were evaluated through an examination of different forecasting options. It was revealed that even noisy estimates of meteorological events improved the flow forecasts. (Author abstract) 7 refs.

**090475 BEDFORM LENGTH AND VELOCITY PULSATIONS IN ALLUVIAL CHANNELS.** It is conjectured that the low-frequency turbulence in alluvial channels is engendered at the separation points of the large eddies in the lee of bedforms. These points are taken as the locations of point sources of pressure disturbances, and their influence throughout the flow region is determined using the normal-mode analysis of the linear hydrodynamic stability theory for inviscid fluids. The analysis predicts that the spatial rate of decay, with respect to depth, of the standard deviation of velocity fluctuations is closely related to the bedform length. The theoretical predictions are borne out reasonably well by the observed data. (Author abstract) 16 refs.

**090477 MODEL OF RIVER FLOW FORECASTING FOR A SMALL FORESTED MOUNTAIN CATCHMENT.** A model for quantitatively expressing the hydrological cycle in a forested mountain catchment is proposed as a HYCYMODEL. HYCYMODEL is able to predict both short- and long-term hydrographs because the model parameters remain independent of time. It shows a good applicability for ten years of continuous data at both hourly and daily intervals for the Kiryu catchment - a forested mountain basin. Since HYCYMODEL does not need hydrograph separation between storm flow and base flow, it is a particularly attractive model. (Author abstract) 52 refs.

Fukushima, Yoshihiro. *Hydrol Processes* v 2 n 2 Apr-Jun 1988 p 167-185.

**090478 EFFECT OF THE CROSS-SECTIONAL SHAPE OF A CANAL ON THE PARAMETERS OF STEEP TRAVELING SURGES.** Steep traveling surges in canals and rivers are formed upon a comparatively rapid change in the discharge of water at the starting or

end site. This is due to opening or closing of gates, change in the operating regime of a hydroelectric station or pumping station, emptying of lock, etc. In an extreme case steep surges of increased intensity are formed upon failure of a dam or other water-impounding structure. The shallow-water wave forming, depending on the rate of change in the discharge at the site and distance from the site, can be discontinuous (in the form of a moving hydraulic jump, which is usually called a bore) or continuous (in the form of a positive surge or negative surge). An analytical solution to reveal completely the degree of effect of the cross-sectional shape of a canal or river on the surge parameters, is presented. 4 refs.

**090479 STEELE BAYOU GRAVITY CONTROL STRUCTURE VICKSBURG, MISSISSIPPI.** A hydraulic model was used to evaluate various schemes to eliminate the severe turbulence and eddies that have caused drastic erosion problems downstream of the Steele bayou drainage structure. Significant bottom scouring and bank sloughing have occurred during the outflows following spring floods. The study was conducted to develop a solution for the excessive scour in the channel reach between Mississippi Highway Bridge No. 465 and the Steele Bayou structure where a 40-ft-deep by 600-ft-wide scour hole developed in the prototype. The longitudinal dikes, recommended as a result of the model tests, were installed in 1985 and have performed well through a period of relatively high water. (Author abstract).

**090480 ALLUVIAL CHANNEL HYDRAULICS.** The regime of any conveyance channel in alluvium depends on the interrelationships of sediment transport, channel resistance and bank stability. The regime concept was originally based on empirical relations. In more recent years the empiricism of the original method has been replaced by process-based methods. The empirical approach to the hydraulics of alluvial channels has been updated by physically based formulae for sediment transport and resistance. Physical modelling using scaled down representations of rivers and estuaries has been used for almost a century, but it requires the correct simulation of the relevant processes. The coming of a better understanding of the physics of sediment transport and the complexity of alluvial channel roughness leads to the conclusion that only in very restricted circumstances can scale models simulate closely the full-size condition. However, the quantification of these processes has been instrumental in the development of computational models which avoid such 'scale effects'. (Edited author abstract). 40 Refs.

## Diversion

**090481 BASIC HYDROLOGIC STUDIES FOR ASSESSING IMPACTS OF FLOW DIVERSIONS ON RIPARIAN VEGETATION: EXAMPLES FROM STREAMS OF THE EASTERN SIERRA NEVADA, CALIFORNIA, USA.** This article describes methods for collecting relevant hydrologic data, and reports the results of such studies on seven stream reaches proposed for hydroelectric development in the eastern Sierra Nevada, California, USA. The methods described are: (a) preparing geomorphic maps from aerial photographs, (b) using well level records to evaluate the influence of streamflow on the riparian water table, (c) taking synoptic flow measurements to identify gaining and losing reaches, and (d) analyzing flow records from an upstream-downstream pair of gages to document seasonal variations in downstream flow losses. In the eastern Sierra Nevada, the geomorphic influence on hydrology and riparian vegetation were pronounced. Examples of which are discussed in the article. 19 refs.

**090482 EFFECTS OF DIVERSIONS ON THE NORTH AMERICAN GREAT LAKES.** A research project evaluated the effects of interbasin diversion on the Great Lakes system and on the industries that depend on the maintenance of historical water levels, namely hydropower and commercial navigation. The simulation approach employed in this research and some of the important findings are presented. The approach is similar to that used in recent government studies of Great Lakes water level regulation. Several significant modifications were made specifically addressing the diversion issue. Aggregate annual impacts to hydropower and shipping resulting from a diversion of 10,000 cubic feet per second were found to vary from 60 to 100 million dollars. Increases in impacts as a function of diversion rate are nonlinear for the navigation industry. (Edited author abstract) 10 refs.

**090483 SEDIMENTATION OF DREDGING CUTS IN SAND BOTTOM RIVERS.** Dredging cuts made in navigable rivers of the USSR when spring flood waters are subsiding, are subsequently sedimented again and dredging operations are required to be repeated. This article deals with some factors causing sedimentation of cuts and states that the main one is the flowing in of soil from lateral slopes of cuts being flattened. A mathematical model of the sedimentation process of cuts based on the analogy between the above process and those of diffusion and heat propagation is shown. The intensiveness of sedimentation is governed by the river sediments discharge. A method of sedimentation forecasting enabling one to calculate the course of cut sedimentation, is worked out. **090486 PROBLEMS OF MONITORING THE ENVIRONMENT OF THE SHALLOW NEARSHORE ZONE OF THE VOLGA MOUTH.** The natural conditions of the shallow Volga nearshore zone and adjacent shallow part of the North Caspian are decisive for the migration, spawning, and foraging of young valuable fish species and for maintaining the ecosystems of the Astrakhan biosphere reserve located in the Volga mouth. Among the main problems of monitoring the natural conditions of this region are monitoring of the dynamics of the drainage network, flooding of the delta shoreline, dynamics of the overgrowth of the mouth nearshore zone

by macrophytes, regime of the currents, water quality, biological productivity, etc. The Institute of Water Problems, Academy of Sciences of the USSR, is systematically elaborating scientific and methodological problems of monitoring (including cartographic) the mouth regions of rivers. The methodological basis of investigating the natural environment of river mouths is the combined use of data of on-site observations, aircraft and satellite multispectral photographs, and other remote-sensing observations. Its possibilities for the Volga mouth are discussed in this paper. 9 refs.

**090487 ASSESSING FLUSHING-FLOW REQUIREMENTS FOR BROWN TROUT SPAWNING GRAVELS IN STEEP STREAMS.** The authors evaluated flushing flows on reaches proposed for hydroelectric diversions on seven streams in the eastern Sierra Nevada, California, with wild populations of brown trout (*Salmo trutta*). Methods for estimating flushing flows from flow records, developed from studies in other localities, produced widely differing results when applied to the study streams, probably reflecting differences in the hydrologic and geomorphic characteristics of the streams on which the methods were developed. Tracer gravel experiments demonstrated that all sampled gravels were washed out by the flows of 1986, a wet year. Size analyses of gravel samples and hydraulic data from field surveys were used in tractive-force calculations in an attempt to specify the flow required to flush the gravels. Results suggest that the tractive-force approach may not be generally applicable to small, steep streams where nonuniform flow conditions prevail. (Edited author abstract) 27 refs.

**090488 PHYTOPLANKTON BIOMASS AND PRODUCTION IN THE RIVER MEUSE (BELGIUM).** The biomass and production of the phytoplankton in a relatively unpolluted reach of the River Meuse (Belgium) were followed through two years (1983 and 1984). Chlorophyll *a* varied from 0.2 to about 120 mg m<sup>-3</sup>, and production ranged between 0.05 and 5.78 gC m<sup>-2</sup> d<sup>-1</sup>. The mean photosynthetic quotient (PQ) was 1.25. The parameters of the light-photosynthesis relationship ( $P_{opt}$  and  $I_k$ ) were calculated and related to the variations of temperature and light in the water column. A simple model allowed calculations of the annual production, which was estimated to be 494 gC m<sup>-2</sup> yr<sup>-1</sup> in 1983 and 547 gC m<sup>-2</sup> yr<sup>-1</sup> + U 1 in 1984. Finally, a simple model is developed, which explains the relationship between phytoplankton development and discharge. (Edited author abstract) 27 refs.

## Energy Resources

**090489 ROLE OF SMALL HYDROELECTRIC STATIONS IN THE RATIONAL USE OF SMALL RIVERS.** The construction of small hydrostations as part of multipurpose water-management systems is planned on the basis of technical and economic calculations with consideration of the requirements of all participants of the complex. The construction of hydrostations on small rivers in mountain regions is most expedient; at the same time it is necessary to cautiously approach the problem of mass construction of small hydrostations on plains, which is related to comparatively large flooding of fertile floodplain lands, siltation of reservoirs, and other undesirable consequences. The construction of small hydrostations can become one of the integral parts of the approach to solving the problem of the most rational use of water

resources of small rivers. 10 refs.

## Environmental Testing

**090490 EVALUATION OF SIZE-DISTRIBUTION EFFECTS AND LABORATORY PRECISION IN THE ANALYSIS OF BOTTOM MATERIALS.** Bottom-material samples were collected at two sites on the Cuyahoga River in Cuyahoga and Portage Counties, Ohio. Multiple samples were collected from one cross section at each site and separated into three fractions based on particle size. Significant differences in metal concentrations were observed within cross sections as well as between sites. The coefficient of variability within the cross-sections decreased as the particle size decreased in the analyses for chromium, copper, iron, and lead, whereas the variability remained constant for manganese and zinc. Metals concentrations, however, generally increased as particle size decreased. An 'index of discrimination' indicated that the less than 20-micrometer fraction was superior for detecting between site-differences in concentrations of metals in the bottom materials. Additional study results are discussed. (Edited author abstract) 14 refs.

Helsel, Dennis R.; Koltun, Gregory F. *Geol Surv Water Supply Pap (US)* 2310 Dec 1986 p 1-11.

**090491 STABILITY OF RHODAMINE WT DYE IN TRIAL STUDIES OF SOLUTE TRANSPORT IN AN ACIDIC AND METAL-RICH STREAM.** Rhodamine WT and sodium chloride were concurrently injected for a period of 24 hours into the naturally acidic water of the Snake River (Montezuma, Colo.). Spatial variations in the concentrations of chloride, sodium, sulfate, and fluoride were observed. The variations are slight; however, they are qualitative indicators of inflow and (or) reactivity in this metal-rich stream. Water samples collected for rhodamine WT determination were stored for several days before analysis. A decrease in fluorescence associated with the water chemistry occurred in the samples obtained in the Snake River above the confluence with Deer Creek. Results obtained in batch experiments support the conclusions of the solute-transport experiment. The apparent stability of the rhodamine WT was time dependent and related to the location of the course of the bulk water from the stream and to whether or not the dye was added immediately after collection of the bulk water. (Edited author abstract) 11 refs.

Bencala, Kenneth E.; McKnight, Diana M.; Zellweger, Gary W.; Goad, Julie. *Geol Surv Water Supply Pap (US)* 2310 Dec 1986 p 87-85.

**090492 DEVELOPING MANAGEMENT GUIDELINES FOR RIVER NITROGENOUS OXYGEN DEMAND.** Incubation studies were used to evaluate the possibility of modeling, the effect of nitrification on river DO. Planktonic nitrification could be modeled by the Monod growth equation. Best-fit Monod parameter estimates showed that planktonic nitrification significantly depletes DO only if reoxygenation coefficient (base *e*) is less than 4 day<sup>-1</sup>, ammonium exceeds 1.5 g/m<sup>3</sup>, and travel times exceeds approximately 9 days. A reliable model of benthic nitrification can only be obtained if a corroboration survey is carried out at a markedly different ammonium load from the initial calibration survey. The wide range in reported decay coefficients and nitrification rates precludes reliable predictions of new ammonium discharge effects on river DO. (Author abstract) 27 refs.

Cooper, A. Bryce. *J Water Pollut Control Fed* v 58 n 8 Aug 1986 p 845-852.

**090493 BENTHIC CHAMBER FOR USE IN RIVERS: TESTING AGAINST OXYGEN MASS BAL-**

ANCES. An in situ benthic chamber has been developed in order to measure rates of respiration and photosynthesis in rivers. Oxygen mass balances for three rivers show satisfactory agreement between chamber and calculated net benthic oxygen uptake rates (BUR) by matching chamber and river boundary velocities (each measured 0.05 m above bed). The BUR is a function of the flow velocity of the overlying water, with both sewage fungus biofilms and pumice sediments each showing a large positive response and approximately linear relationship to velocity over the range studied. Measurements of the oxygen mass transfer coefficient for the air-water interface of an inverted chamber showed that the response to flow velocity was not significantly different from that predicted using the D.J. O'Connor-W.E. Dobbins formula. (Edited author abstract). 53 Refs.

**090494 RELATIONSHIP BETWEEN GLACIAL GEOLOGY AND STREAMWATER CHEMISTRY IN AN AREA RECEIVING ACID DEPOSITION.** Seventy streams in southwestern New York State were sampled in June and again in December. Streamwater chemistry proved to be closely associated with glacial geology. Streams in glaciated area watersheds had higher pH, alkalinity, calcium, and conductivity values than streams in unglaciated area watersheds. Within the glaciated area, streams of the Kent Drift Sheet had higher alkalinity, calcium, and conductivity values than streams of the Olean Drift Sheet. Streamwater sulfates were also analyzed in December, and were found to be highest in the Kent Drift Sheet. Glacial geology of a watershed is well predicted by discriminant analysis of streamwater chemistry data. Additional buffering capacity provided by glacial till appears to override sulfate adsorption considerations in making the glaciated area streams less susceptible to atmospheric acid deposition. (Author abstract). 17 Refs.

**090495 SINK OR DRAIN: A SIMULATION STUDY OF FACTORS AFFECTING THE ROLE OF AN ESTUARY SUBJECT TO TOXIC INPUTS.** In response to a shift in its mean influx, the concentrations of a refractory substance in an estuary will tend from some initial steady state (subject to environmentally induced variation) to a new level. In the 32 km Tamar Estuary, a partly-mixed estuary in southwest England, the timescale of this transition appears to be <10-20 years. The present paper describes the use of a published numerical model of pollutant dispersal in the estuary to investigate the dependence of this evolution on the mean levels and variation in space and time of the physical and chemical determinants of the system. (Author abstract) 6 refs.

Harris, J.R.W. (Inst for Marine Environmental Research, Plymouth, Engl). *Water Res* v 21 n 8 Aug 1987 p 975-981.

**090496 PLUTONIUM AND CESIUM RADIONUCLIDES IN SEDIMENTS OF THE SAVANNAH RIVER ESTUARY.** A study was made of the <sup>239</sup>Pu, <sup>240</sup>Pu, <sup>238</sup>Pu and <sup>137</sup>Cs concentration in tidal marsh sediments of the Savannah River estuary. Tidal marshes are identified as special locations for plutonium deposition because of the high biological productivity and relative stability of sediments as compared to channel sediments.

The  $^{239,240}\text{Pu}$  deposition averaged  $3.2 \text{ mCi km}^{-2}$ , which is higher than land-based fallout value of about  $2 \text{ mCi km}^{-2}$ . The  $^{239,240}\text{Pu}$  to  $^{137}\text{Cs}$  ratio was about three times higher than fallout deposition estimates, indicating a more rapid desorption of  $^{137}\text{Cs}$  from sediment in the saline waters of the area. (Author abstract) 8 refs.

**090500 COMPUTATION OF SEDIMENT CONCENTRATION IN THE QIANTANG ESTUARY WITH CONSIDERATION OF SEDIMENT TRANSPORT IN TIDAL FLAT.** The authors discuss a wide tidal flat in the Qiantang Estuary. In this article the sediment concentrations in the mainstream and on the tidal flat are computed separately, taking into account the transverse exchange of sediment between them. The ratio of the bottom sediment concentration to the vertical average is not taken as the same to the ratio of sediment transport capacity. The ratio of sediment concentration can be determined by the computational results of a simple model and checked by the field data. The formula of the sediment transport capacity for tidal flow can be obtained by statistical analysis directly using the measured values of sediment concentration. The verification of sediment concentration has been carried out with two sections both in the mainstream and on the tidal flat during twelve successive tidal cycles. The average discrepancy between the calculated and the measured is less than

20%. (Edited author abstract) 6 refs.

**090501 POTENTIAL EFFECTS OF DREDGING ACTIVITIES AND INCREASED SILT LOAD ON THE ST. LUCIA SYSTEM, WITH SPECIAL REFERENCE TO TURBIDITY AND THE ESTUARINE FAUNA.** Turbidity regimes within the St. Lucia Estuary were investigated over a period of three and a half years. At the same time the potential effects, in terms of increased turbidity and silt load, of the Umfolozi River/St. Lucia Estuary Link Canal were assessed. The possible effects on the fauna of the system are further emphasized by comparison with the effects of dredging on estuarine faunas in other parts of the world. Recommendations are put forward suggesting that impact studies be undertaken before the Link Canal is fully inaugurated. Impact studies should also be carried out to determine the effects of continued dredging on the estuary. (Author abstract) 25 refs.

**090502 JOINT PROBABILITY DISTRIBUTION OF STREAMFLOWS AND TIDES IN ESTUARIES.** A procedure for estimating the joint probability of occurrence of correlated extreme tides and corresponding freshwater flows in estuaries is presented. The method uses the G.E.P. Box-D.R. Cox transformation to transform the original data to near normality, and therefore the search for a parent distribution is avoided. It is also shown that the traditional assumption of statistical independence for the jointly distributed random variables may lead to the underestimation of flows and tidal heights. The methodology is applied to the Rappahannock River in Virginia which flows into the Chesapeake Bay. (Author abstract) 12 refs.

**090503 DEVELOPMENT OF MANUALLY USEABLE COMPOSITE MATERIALS FOR RIVER TRAINING WORKS IN HOOGHLY ESTUARY.** The training works in the Hooghly estuary required construction of spur walls in limited working season in a year with constraints regarding labour, materials and machinery and achieving stabilization of construction against onslaught of high current and wind. This paper describes some of the composite materials that have been evolved based on standpoints of local availability, economy, feasibility and rapidity of construction in time-bound working period with local labour and equipment. **090504 HYDROLOGY AND HYDRODYNAMICS OF THE ODRA ESTUARY WITH SPECIAL REFERENCE TO THE INFLUENCE OF WIND.** The article presents the factors which constitute the hydrology and hydromechanics of river mouths with special attention paid to the effect of wind, this being of great importance for the estuary of the Odra. Analysis of this phenomenon enabled to form a mathematical model of a tachoid with the influence of wind taken into account and to introduce it into the mathematical model of the Odra estuary in order to define the phenomenon of wind backwater. Technical aspects of wind backwater have been presented with special attention paid to the safety of navigation, protection of aquatic environment and flood protection. (Author abstract) In English and French. 10 refs.

**090505 HYDRODYNAMIC CONDITIONS AND**

**SALINITY OF THE SWINA STRAIT AND THE SZCZECIN BAY.** The article describes certain characteristics of the Odra estuary and presents the various phases and the results of research carried out in this region during the last 40 years. In a more detailed manner, it presents the conditions and results of the expeditions performed in the years 1983 and 1985. The data obtained therefrom have made it possible to determine the prevailing hydrodynamic conditions and the salinity character of waters in the Swina Strait and the Szczecin Bay. The article also gives the results of theoretical analyses performed on the basis of ground surveys. Lastly, the authors describe the unsettled character of the velocity distribution in the Swina Strait, a fact which impedes navigation. (Author abstract) In English and French. 9 refs.

**090506 MATHEMATIC MODEL OF THE RIVER ODRA ESTUARY.** A mathematical model of the Odra estuary, the aim of which is simulation of determined and undetermined processes in hydrodynamics of this estuary is presented. The dynamic phenomena at the mouth of the Odra being of importance in the economic human activity and the necessity of building such a model are discussed. Then the general idea of an aggregate model aimed at is described. In subsequent parts descriptions are given of the actual state - the construction and operation of the model of determined and undetermined motion in the river part of the Odra estuary and of the base of hydrological and meteorological information 'HIMOS'. The article is completed by examples of results obtained for the actual swells and by conclusions and suggestions regarding the further development of work in this field. (Edited author abstract) In English and French. 26 refs.

**090507 LOWER JAMES RIVER CIRCULATION STUDY, VIRGINIA, EVALUATION OF CRANEY ISLAND ENLARGEMENT ALTERNATIVES.** This report presents results from the numerical model investigation whose primary objective was to assess general changes in circulation, currents, and sedimentation associated with six proposed alternative expansion geometries of the Craney Island confined disposal facility. An additional objective of the study was to assess the effects of each of the six alternative geometries on the reported estuarine circulation cell (flow convergence) off Hampton Flats and Newport News Point. This numerical model investigation used the TABS-2 finite element numerical models RMA-2V for hydrodynamics and STUDH for sedimentation with a modified version of an existing numerical mesh of the Lower James River. Other information presently available regarding the estuarine circulation and flow convergence observed off Newport News Point and Hampton Flats was reviewed. Results from the numerical sedimentation modeling showed that plan to base shoaling index values (plan-predicted sedimentation divided by base-predicted sedimentation) were all within 90 to 110 percent at the critical areas of interest. (Edited author abstract) 14 refs.

**090509 INVENTORY OF TRAINING STRUCTURES IN ESTUARIES.** This report inventories training structures in estuaries. The ultimate goal of the research is to improve design guidance for the effective use of training structures in estuaries. This inventory is the result of literature and map surveys to determine what structures exist in the estuaries and is the first of three planned stages of research. Several structures will be selected for further detailed data retrieval. The structures will then be modeled in both a physical model (flume) and a numerical model. The resulting product will be a numerical method verified by prototype and physical model data to assist during the design stage for estuarine training structures. The method will also aid engineers in determining the effectiveness of existing structures. (Author abstract). 17 Refs.

**090510 TEJO 1 - AN INTERACTIVE PROGRAM FOR THE DIVISION OF ESTUARIES INTO HOMOGENEOUS AREAS.** The division of an estuary into homogeneous areas from both hydrodynamic and ecological standpoints is essential to any estuarine basin management model. This paper presents an approach based on a heuristic algorithm to achieve such a division. The methodology implemented through an interactive computer program named Tejo 1 applies morphological, water quality and management criteria in order to achieve the disaggregation. The approach is equally applicable to river or lake basins, with only minor adaptations. An application of Tejo 1 to the Tejo estuary is included for illustrative purposes, which resulted in the final division of the estuary into 11 homogeneous areas. (Author abstract) 6 refs.

**090511 TOWARDS CONTROL OF AN ESTUARY.** The Delta Project is in its final stage. In 1974 it was subjected to political reconsideration, but it is scheduled now for completion in 1987. This article focuses on the area with reduced tide and compares present day and expected characteristics. In this reduced tidal part salt marshes will extend by 30-70%; intertidal flats will erode to a lower level and at their edges, and the area of shallow water will increase by 47%. Biomass production on the intertidal flats will decrease, with consequences for crustaceans, fishes and birds. The operation of the storm-surge barrier and the closure strategy chosen are very important for the ecosystem. Two optional closure strategies can be followed without any additional environmental consequences. It was essential to determine a clearly defined plan of action for the whole area, and to make land-use choices from the outset. How this was done is briefly described. (Edited author abstract) 25 refs.

## France

**090512 EVOLUTION OF THE CHEMICAL COMPOSITION OF THE GARONNE RIVER WATER DURING THE PERIOD 1971-1984.** The evolution of the chemical composition of the Garonne River water was studied for the period 1971-1984. The large increases of  $\text{NO}_3^-$ ,  $\text{SO}_4^{2-}$ ,  $\text{Cl}^-$  and  $\text{K}^+$  in the river water are related to a marked increase in fertilizer applications.  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$  and  $\text{HCO}_3^-$  increases are not so evident. The coefficient of calcite saturation is too low to explain this change but rather it can be attributed to an increase in carbonate dissolution resulting from the nitrification of N fertilizers in the basin. A decrease in pH, more particularly during low flows, is attributed to oxidation of organic matter which is reflected by an increase in COD. (Edited author abstract) 22 refs.

## Friction

**090513 FRICTION FACTOR EVALUATION IN GRAVEL-BED RIVERS.** Field data gathered from 43 river reaches of Calabria (southern Italy) were employed to develop a theoretically based equation for predicting the f-friction factor that takes into account both the Froude number and the sediment mobility parameter. The river reaches investigated have: (1) reasonably uniform and relatively low flow; (2) no appreciable vegetation in the channel bed and banks; (3) a fully developed turbulent flow; (4) a friction slope greater than 0.2 percent; (5) small and intermediate scale roughness; (6) a mobility parameter greater than the critical value in more than 50 percent of the cases; and (7) a Froude number between 0.20-1.30. Statistical techniques were used to derive an equation for estimating f that takes into account the physical processes controlling flow resistance beyond the range of the collected data. (Author abstract). 40 Refs.

## Ganga River

**090514 MONITORING OF HEAVY METALS IN THE WATER AND SEDIMENTS OF THE GANGA RIVER, INDIA.** The concentrations of cadmium, cobalt, chromium, copper, iron, manganese, nickel, lead and zinc in the water and sediments of the Ganges river were determined by Atomic Absorption Spectrophotometry in the year 1981. The respective ranges of concentration of cadmium, cobalt, chromium, copper, iron, manganese, nickel, lead and zinc found in the water were ND-0.53, ND-4.89, 3.20-56.6, ND-27.57, 22.0-133.8, 35.0-93.0, ND-2.22, 2.0-5.6 and 7.37-67.36  $\mu\text{g/l}$  and in the sediments were ND-3.48, 2.35-14.4, 9.0-83.16, 11.27-95.0, 2168.0-11624.8, 110.5-470.0, 3.45-28.80, 0.55-21.8 and 72.0-418.6  $\mu\text{g/g}$ . The data showed that there was considerable variation in the elements from one sampling station to the other. The sediments collected from different sampling stations were also analyzed for pH, calcium carbonate, organic matter, potassium and phosphorus. (Author abstract) 36 refs.

## Hungary

**090516 ZALA-VIZGYUJTO FAJLAGOS LEFOLYASIS VIZSZONYAINAK VIZSGALATA.** [Investigation of the Conditions of Specific Runoff in the Catchment of the Zala River]. With regard on existing gauging stations with longer observation periods, the catchment of the Zala river was divided into 6 sub-catchments. On the basis of multiannual average precipitation data the precipitation-runoff relationship was determined for each sub-catchment. The sub-catchments were then subdivided again and the values of specific average low-flow runoff were calculated based on low-flow measurements and estimates, and on the 'individual behaviour' of existing brooks. Finally, the runoff values - obtained by the different methods - were compared to each other and the following result could be drawn down: the error in the value of specific multiannual average runoff was 5 percent in case of the catchments with high runoff, and 15 percent with a small one, respectively. (Edited author abstract) 5 refs. In Hungarian.

**090517 REPRESENTATION OF FLOWS TO PARTIALLY PENETRATING RIVERS FROM LAYERED AND ANISOTROPIC AQUIFERS.** It has previously been shown that it is possible to represent the flow of water from a homogeneous, isotropic aquifer to a river or drain by using a Dupuit-Forchheimer groundwater flow model coupled with equations to calculate the magnitude of the flow to the river. This work has now been extended to include anisotropic and layered aquifers. Results obtained from two-dimensional free surface seepage models are used to assess the accuracy of the results from the Dupuit-Forchheimer models. It is shown that such models can be used to accurately estimate the flow to a river for a wide variety of situations. (Author abstract) 11 refs.

## Ice Formation

**090518 CHARACTERISTICS OF ICING OF THE WESTERN ZONE OF BAM DEVELOPMENT ACCORDING TO AERIAL AND SATELLITE DATA.** Discussed in the variation of icing of river basins in orographically identified regions of the Stanovoi highlands, the Vitim tablelands, and the Olekminskii Stanovik. Principles are identified in the variation of icing characteristics for various areas of river basins, on slopes of ranges of different exposure. The icing of basins of the Vitim and Olekma Rivers and the northern area of Lake Baikal. A map of water reserves in the ice (in mm) has been compiled from results from processing remote sounding materials. (Author abstract) 3 refs.

Abakumenko, A.E. *Sov Meteorol Hydrol* n 2 1987 p 72-76.

**090519 PERTURBATION BASED MODEL OF HEAT-INDUCED SUPPRESSION OF RIVER-ICE.** The discharge of tributary thermal effluents into cold region rivers may alter the thermal and hydrodynamic conditions of ice cover progression and create reaches of open water in the ice throughout the winter season. An analytical approach, based on perturbation techniques,

has been developed and tested concerning the suppression of ice cover and the migration of its fronts. The upstream and the downstream ice edges are determined for two cases of steady non-uniform flow. Conditions for the suppression of the ice cover are also obtained based on the relative positions of the upstream and downstream ice edges. Comparison with field data shows a good agreement with the formulation incorporating the thermal effluent velocity. (Edited author abstract) 12 refs.

## Improvement

**090520 RESTORATION OF HEAVILY POLLUTED BRANCHES OF THE SHATT AL-ARAB RIVER, IRAQ.** In view of the desire to improve the water quality of the heavily polluted branches of the Shatt al-Arab river at the City of Basrah, it was proposed to maintain effective flushing as well as contracting sewerage system. The present study was conducted in order to examine the water quality of these branches in an attempt to evaluate the effectiveness of the proposed flushing system. It has been found that their waters contained very low levels of dissolved oxygen and relatively high amounts of both COD and BOD<sub>5</sub>. Based on our calculations, it has been concluded that the proposed system is effective, thus within a flushing cycle all of the above mentioned parameters will become within the acceptable values of the Shatt al-Arab water quality. Moreover, this system has no appreciable effect upon the water quality characteristics of the Shatt al-Arab River due to the fact that it discharges a high volume of water annually. It has been recommended to dredge the deposited sludge to a minimum depth of 50 cm. (Edited author abstract) 8 refs.

DouAbul, Ali A.Z. (Univ of Basrah, Basrah, Iraq); Abaychi, Jamal K.; Al-Asadi, Manal K.; Al-Awadi, Haytham. *Water Res* v 21 n 8 Aug 1987 p 955-960.

## India

**090521 MEASUREMENT OF ADVENTITIOUS STREAMS IN YAMUNA-PAISUNI INTER-STREAM REGIONS (U.P. & M.P.), INDIA.** An attempt has been made to measure the adventitious streams of 20 drainage models of Yamuna-Paisuni inter-stream regions. These streams are caused by topographical and lithological variations as well as structural peculiarities of the region. The measurement has been done on the basis of the topographical sheet and the nature and characteristics of the stream are checked by field observation. (Edited author abstract) 1 ref.

Prasad, Govind (SGR Post-Graduate Coll, UP, India). *Modell Simul Control C* v 8 n 4 1987 p 61-64.

**090522 TEMPORAL, SPATIAL AND SIZE VARIATION IN THE SEDIMENT TRANSPORT IN THE KRISHNA RIVER BASIN, INDIA.** The total sediment transport of the Krishna River to the Bay of Bengal is estimated to be  $4.11 \times 10^6$  ton  $\text{yr}^{-1}$ . The sediment load decreases sharply from  $67.72 \times 10^6$  ton  $\text{yr}^{-1}$  from the upstream region (Morvakonda) to  $4.11 \times 10^6$  ton  $\text{yr}^{-1}$  at the river mouth (Vijayawada). The depletion of sediment supply in the river mouth and lack of uniformity in sediment transport within the basin is mainly due to several human activities. One of the tributaries of the Krishna, the Bhima River is the main sediment contributor to the Krishna. Erosion rate shows no systematic relationship either spatially or temporally. The total sediment erosion of the Krishna is estimated to be  $16 \text{ ton km}^{-2} \text{ yr}^{-1}$ . The particle size distribution of the suspended sediments were correlated with the mean monthly sediment transportation to evaluate the downstream and temporal variation of grain size with sediment transport. Additional study results are discussed. (Edited author abstract) 18 refs.

Ramesh, R. (Jawaharlal Nehru Univ, New Delhi, India); Subramanian, V. *J Hydrol* v 98 n 1-2 Mar 15 1988 p 53-65.

**090523 SEDIMENT TRANSPORT OF THE GODAVARI RIVER BASIN AND ITS CONTROLLING FACTORS.** The mean annual water flow and sediment transport of the Godavari River are estimated to be  $92 \text{ km}^3$  and  $170 \times 10^6$  ton (t), respectively. In terms of sediment transport and the rate of physical erosion ( $555 \text{ t km}^{-2} \text{ yr}^{-1}$ ), the position of the Godavari would be ninth and fifth respectively among the world rivers. Geology of the basin is the main controlling factor of the sediment transport. The sedimentary rocks located in the lower part of the basin and constituting 77 percent of the total basin area are responsible for 33 percent of the sediment load. More than 67 percent of sediment load is silt and clay. Annual, monthly and daily variations in sediment transport indicate that a few selected days in the hydrological year control the annual sediment budget. Our latest estimates are nearly twice that of our earlier values. The presently available global estimates on sediment transport need to be re-evaluated. (Author abstract) 35 Refs.

## Italy

**090524 OSSERVAZIONI SULLA DINAMICA DI UN CORSO D'ACQUA TORRENTIZIO SUSEGUENTE UN EVENTO ALLUVIONALE.** [Observations on the Dynamics of Torrential Water Flow after a Flood Event]. After the flood of August 7, 1978 which took place in the Vigizzo Valley, situated in the most north-eastern part of Piedmont, the Melezzo Orientale river has undergone both transversal and longitudinal intervention to re-lay its bed. Work was carried out on the river's median section over a distance of about 3 kilometers. This summary reports on the river's behaviour after re-laying was completed and how it has responded to floods which have reached maximum levels comparable to the one in 1978. The influence that the environment has on the river's dynamics provides useful information for planning similar re-laying interventions of hydro-geological nature. (Edited author abstract) 19 refs. In Italian.

Quaglia, M. (Politecnico di Torino, Italy); Teslesca, P.; Fadda, M. *G Genio Civ* v 125 n 4-6 Apr-Jun 1987 p 97-111.

## James River

**090525 UPPER JAMES ESTUARY - A STUDY IN WATER QUALITY MANAGEMENT.** The major factors contributing to water quality problems below the City of Richmond stem from the intermittent discharge from combined sewer overflows (CSOs) coupled with the continuous discharge from the City's sewage treatment plant. The CSOs contribute a large quantity of soluble BOD, suspended solids, settleable solids, and fecal coliforms to the estuary. The City's sewage treatment plant continuously discharges large quantities of ammonia-nitrogen and phosphorus, in addition to BOD and suspended solids. Rational Management and use of the waters of the upper James estuary appear to be critical. The objectives of this paper are the discussion of the present water quality and the wastewater discharge reductions required in order to meet certain water quality and water use objectives. (Edited author abstract) 10 refs.

## Locks

**090526 GALLIPOLIS LOCK INTAKE VORTEX STUDY OHIO RIVER.** The existing Gallipolis Locks are located on the Ohio River at mile 279.2. Because of their location on an inside bend, the orientation for approach channels, velocity currents in the river, and the design of the approach walls, entry of downbound tows

into the lock is hazardous and time consuming during periods of high flow. As a result of increasing traffic and tow sizes, these locks will be constructed in the near future to alleviate these problems. Tests were conducted on a 1:25-scale model that reproduced 2,500 ft of the Ohio River beginning 188 ft upstream of the existing lock guide wall. This model was used to evaluate the performance of the intake structures for the new locks. (Edited author abstract)

## Management

**090527 MANAGEMENT OF THE RIVER RHINE.** The Rhine is an international river, which is being used for many different purposes such as drinking water supply, navigation, discharge of wastewater, fishing and recreation. Above all it is an important aquatic ecosystem and part of the environment and landscape. The question was how to manage such a river related to so many different interests and flowing through so many different countries? As in every management case, first of all the aim or goal should be set. The aim is to get the river clean and to maintain it that way, free from persistent toxic substances and generally of a quality which will allow healthy fish life (salmon) and recreation. The quality should be such that it allows for the preparation of healthy drinking water by natural processes, such as rapid and slow sand filtration. The water should not be heated by thermal pollution. This aim should be laid down in specific requirements valid for the whole Rhine catchment area and accepted by the riparian states.

**090528 MANAGING AND ENGINEERING RIVERS FOR THE BENEFIT OF MAN.** From earliest times flood, famine and drought have been scourges of mankind. River engineers alleviate floods, drain the land for agriculture, and conserve water resources. They construct engineering works, guide planners and developers, and provide warnings to minimize damage caused by storms over catchments and coasts. As the country becomes more developed, problems of reconciling conflicting interests require a flexible approach. This paper examines ways of providing the basic services in a climate of increasing public clamour for wildlife and landscape protection, and recreation. (Author abstract) 15 refs.

**Mathematical Models** See Also HYDRAULIC STRUCTURES—Computer Aided Design; WATER POLLUTION—Water Quality.

**090529 USE OF CURRENT METERS FOR CONTINUOUS MEASUREMENT OF FLOWS IN LARGE RIVERS.** Flows in the unregulated Great Lakes connecting channels, the St. Clair and Detroit Rivers, are normally determined using mathematical flow models with calibration based on periodic discharge measurements taken during the open-water seasons. Consequently, the calculated flows normally exhibit good accuracy during ice-free periods, but may contain large errors during winter months with extensive ice cover. The St. Clair River is particularly prone to large ice jams because of practically unlimited ice flow supply provided by Lake Huron and an extensive river delta that retards the passage of these ice flows. This study describes the experimental results of continuous flow measurements using electromagnetic (EM) current meters and an acoustic Doppler current profiler (ADCP) meter during 1983-1985 period. A record ice jam in the St. Clair River occurred in April 1984 and provided an excellent opportunity for testing the current meter program. Verification of current meter results was provided by flows transferred

from the Detroit River, which was ice-free and permitted accurate flow simulation. (Edited author abstract) 5 refs.

**090530 IL MODELLO PARABOLICO DELL'EVOLUZIONE DEL FONDO DI UN CORSO D'ACQUA NATURALE. STUDIO DELL'EQUAZIONE DIFFERENZIALE A COEFFICIENTE COSTANTE. PARTE I.** [Parabolic Model of Evolution of a Natural Stream Bed. Study of a Differential Equation with a Constant Coefficient - I]. Evolution of the natural stream bed, formulated schematically to reflect a complex physical reality, is governed, as is well known, by a partial differential equation, similar to the heat transfer equation. The coefficient which is effectively constant in the latter equation has been retained constant also for the stream flow phenomenon by many researchers to make possible integration of the equation analytically. By using an analytical and numerical approach, it is shown that this coefficient can be considered constant with optimal approximation, and that its value, initial conditions being equal, depends on the final configuration attained by the water course which is the object of the altimetric evolution. Expressions for its evaluation are examined and orders of approximation are identified. (Edited author abstract). 11 Refs. In Italian.

**090532 SOLUTE CONCENTRATIONS IN THE LOWER NIGER RIVER AND THE SOURCE ROCK CONTRIBUTION.** Water quality analyses for the Niger River for the 1980/81 hydrological year are presented. The samples were collected from the main river at Lokoja, and from two main tributaries, the Kaduna and the Benue Rivers. Different water types were distinguished by the concentrations of major ions. Distinct patterns of seasonal variation in the ion concentrations were observed, particularly for the samples collected at Lokoja. Low ion concentrations were prominent during periods of high discharge, while low flow periods coincided with high dissolved ion concentrations. Geochemical weathering calculations involving reactions of the four major minerals of granitic rocks - anorthite, biotite, albite, and K-feldspar - with carbon dioxide and water, can account for the average water composition of the Lower Niger. The proportion of the ionic components was also related to the

occurrence of the respective element in the minerals. (Edited author abstract) 17 refs.

## Norway

**090533 NORWEGIAN RIVER PROTECTION SCHEME: A REMARKABLE ACHIEVEMENT OF ENVIRONMENTAL CONSERVATION.** A dominant feature in the history of nature conservation in Norway has been the struggle to protect some of the most scenic and scientifically valuable river catchments from being exploited for hydropower development. The hydropower-producing potential of these rivers represents one of the most valuable economic resources of the nation, and has been a key factor in the transition of Norway from an agricultural to an industrial society. Viewed against this background of conflicting values, the efforts to set aside a number of representative river systems for purposes other than hydropower development have been one of the dominating environmental issues for the past few decades. 10 refs.

**Odra, Poland** See Also INLAND WATERWAYS—Odra, Poland.

**090534 RIVER ODRA - ITS IMPORTANCE FOR THE NATIONAL ECONOMY.** The article deals with problems of the river Odra as an economic axis, and analyses various aspects such as the needs of water consumption, commercial and pleasure navigation of this region. Because of their particular interest, the author has mainly stressed the transport needs, specially related to the Odra waterway. The length of the waterway from Kozle to the Baltic Sea is 755.2 km and its particular sectors fit into different classes of navigable waters. Canalized in its upper part (187 km), it is regulated over its whole length. The article also gives the actual state of development, the achievements which enabled to reach this state and the prospects aimed at obtaining class IV status of navigable water on its whole length. In brief it also refers to the region's favorable conditions for the development of tourist and recreation activities. (Author abstract) In English and French.

Kwapiszewski, Andrzej (Water Management Office, Pol). *Bull Perm Int Assoc Navig Congr* n 60 Jan-Mar 1988 p 10-16.

**090535 REGION OF THE ODRA ESTUARY AND ITS CONNECTIONS WITH THE HINTERLAND.** The system and parameters of fairways of the Odra estuarine region have a direct effect on the volume of port transshipments, both in sea - and in inland navigation. In the years 1945-1987 a considerable development of port infrastructure took place in the region. This is partly because the size of vessels in operation in the region of the Odra estuary has increased. This in turn, has brought about the need to enlarge the fairway parameters. The increased activity of small ports and the development of inland navigation in this region have been determining factors for deciding the layout of new fairways and the most adequate markings to ensure the safety of navigation. (Author abstract) In English and French. 5 refs.

Jagniszczak, Igor (Maritime Coll of Szczecin, Pol). *Bull Perm Int Assoc Navig Congr* n 60 Jan-Mar 1988 p 46-55.

**090536 MODERNISATION DE LA RIVIERE ODRA EN TANT QUE VOIE NAVIGABLE.** [Modernization of River Odra as a Navigable Waterway]. Due to the important regulation works realized between 1874 and 1885, that period is considered as the first significant stage in the adaptation of the Odra River for navigation purposes. Since then, various sections of that river have gradually been regulated. Nowadays, reconstruction works are carried out on that waterway: new sector barrages have been built in place of the dams with frames and needles and most of the small locks have already been

transformed into big sluices for tows of barges. The realization of such a program - although carried out with a certain delay because of the economic crisis - will guarantee a continuity and better conditions of navigation on the Odra. Examples of reconstruction of weirs are presented at the end of the article. (Author abstract).

## PO River

**090537 RECENT DEPOSITS AND SUSPENDED SEDIMENTS OFF THE PO DELLA PILA (PO RIVER, MAIN MOUTH), ITALY.** Present sedimentary conditions in the prodeltaic marine area immediately in front of the Po della Pila (Po River main mouth) are characterized by a maximum thickness of Holocene muds of 10-12 m at a depth of 20-25 m and by two different sedimentary cycles, with the more recent lens-shaped unit (2.5-4.0 m thick) probably deposited in the last 300 yrs. The nearshore prodelta area is characterized by rapidly accumulating deposits (2-4 cm/yr) enriched in smectite, gas, organic material (1-2%) and trace metals. The water system presented well marked vertical stratification during the summer of 1985, revealing three distinct water bodies: (1) riverine and diluted waters (average depth of 3 m), (2) middle depth waters (10-20 m) and (3) bottom waters. (Edited author abstract) 37 refs.

## Remote Sensing

**090538 LANDSAT-MSS RADIANCE AS A MEASURE OF SUSPENDED SEDIMENT IN THE LOWER YELLOW RIVER (HWANG HO).** A method of converting the Landsat-MSS radiance to an estimate of suspended sediment concentration is presented. The CCT data for the Lower Yellow River (Hwang Ho) were used in the study. The data were first corrected for instrumental error due to a drift in the sensor response and then converted to the absolute radiance received by the sensor. In order to understand the detected radiance and its variability, radiative transfer in the earth's atmosphere and natural waters are discussed. The radiative transfer equation has been simplified, so that a highly accurate atmospheric correction algorithm for diffuse sky radiance may be developed. (Edited author abstract). 27 Refs.

## Rhine River

**090539 DIE IAWR UND IHR ZWEITES RHEIN-MEMORANDUM 1986.** [IAWR and the Second Memorandum on the River Rhine in 1986]. The river Rhine traverses an industrialized densely populated region of Central Europe and carries a burden of multiple uses and pollutions. By cooperation of the water distribution companies in the IAWR (International Working Party of the Waterworks in the River Rhine Basin) since 1969, guidelines for rehabilitation of the Rhinewater quality were worked out, published in the first 'Memorandum of the IAWR' in 1973. Since about 1980, the conditions have improved in general, but the characteristics of pollution have changed. The second 'memorandum', published in 1986, summarizes the topical requirements of the waterworks on Rhine protection policy. (Author abstract) In German.

**090540 DIE TRINKWASSERVERSORGUNG AM RHEIN NACH DEM SANDOZ-UNFALL.** [Drinking Water Supply from the River Rhine After the Sandoz-Accident]. The Sandoz accident of November 1st, 1986 did not cause significant damage to the infiltration paths where bank infiltrated water seeps to the wells of the water works. In some cases operational measures undertaken by the water works in an early stage provided an effective protection against the pollution wave in the river Rhine. Investigations proved moreover that underground passage and the filtration of the withdrawn water through activated carbon guaranteed a sufficient protection against a nuisance of drinking water supply. Despite this positive review there have to be drawn far-reaching conclusions from the Sandoz accident concerning the water protection policy and improved measures of hazard defence in the view of public drinking water supply. (Author abstract) In German. 7 refs.

**090541 ANFORDERUNGEN AN DIE RUHR AUS DER SICHT DER TRINKWASSERVERSORGUNG.** [Ruhr Water Quality Requirements from the Point of View of Drinking Water Supply]. The water resource Ruhr is run by the Ruhr River Association and the Ruhr Reservoirs Association. The water-works on the Ruhr cover the needs of drinking water of approx. 5 mill. people. Therefore there is no need to part from the principle of self-administration supervised by government. However, action should be taken with respect to the raw water quality. Facing the crucial importance of river Ruhr to the drinking water supply, further steps should be taken to improve the raw water quality. Deficits in raw water quality are described. (Edited author abstract) 15 refs. In German.

Scherer, Peter (Gelsenwasser AG). *GWF Gas Wasserfach Wasser Abwasser* v 129 n 4 Apr 1988 p 232-235.

**090542 MINIMIERUNG DER SCHADSTOFF-BELASTUNG DER RUHR.** [Minimizing of the Pollutant Load on the River Ruhr]. The river Ruhr has to serve as recipient for the (purified) wastewaters of a densely populated industrial area. So it is loaded with a variety of pollutants (organic matter, nutrients, toxic and noxious substances). As the small river has to serve as purveyor for the drinking water supply as well, the loading has to be reduced as far as possible. To achieve this the different sources of pollutants have to be traced. The success and the future problems of water quality management are demonstrated exemplarily for the different types of pollutants. Especially in the case of trace constituents legislative measures are needed, e.g. for the production and application of pesticides. (Author abstract) In German.

**090543 SOME SORPTION PROPERTIES OF NILE SILT.** The sorption properties of heat-treated Nile silt were investigated using thermoanalytical, X-ray diffraction, and spectroscopic techniques. After heat treatment at 650°C, the silt shows remarkable sorption properties for both organic, e.g. 3,6-bis-dimethyl-amino acridine hydrochloride, and inorganic, e.g. Cu<sup>2+</sup> cations. The cation uptake from chloroform and dichloromethane solvents is highly efficient but from protic solvents such as methanol or water it is insignificant. There is also a slight uptake of crude oil by the silt, a fact which may be useful in the fight

against oil pollution. The purity of the chloroform and dichloromethane was improved enormously after passing through columns of the heat-treated silt and this could be of industrial significance. This work is also pertinent to solvent purification and water treatment. (Edited author abstract) 7 refs.

**090544 SEDIMENT TRANSPORT, EROSION AND DEPOSITION IN RIVERS DUE TO OVERLOADING.** The paper presents a depth-averaged model for the sediment transport in natural flows based on 2-D diffusion equation, which is discretized following the solid matter transfer due to liquid exchange. The model is applied for the alluvial transport close to the equilibrium state of the 100 km segment of the Danube river upstream the 'Iron Gates I' dam and compared to a modified version of the Toffaleti model. Then the model is applied for the same segment in the case of heavy overloading with artificial sediments. (Edited author abstract) 9 refs.

**090545 EFFECTS OF HYDROLOGICAL FACTORS ON RIVER SUSPENDED SOLIDS CONTAMINATION FROM A COLLIERY IN SOUTH WALES.** Field studies over a 16 month period found that concentrations below the colliery ranged from 4 to 8028 mg l<sup>-1</sup>. Simple correlation and linear regression analysis of spot and storm event samples taken below the colliery gave a correlation coefficient of 0.39 between flow and suspended solids concentration. Because of the lack of explained variance, a multiple linear regression model of within-storm concentrations was derived using four selected independent variables. X<sub>1</sub> the time relation of the sample to the storm peak; log X<sub>2</sub> the stormflow at the time of sampling; log X<sub>3</sub> the baseflow at the time of sampling; and log X<sub>4</sub> an index of the storm intensity. Analysis of the entire dataset gave an R<sup>2</sup> of 0.34. When the results from three atypical events were excluded, however, the R<sup>2</sup> value improved to 0.65. Additional study results are discussed. (Edited author abstract) 51 refs.

**090546 BOAT TRAFFIC, SEDIMENT RESUSPENSION AND TURBIDITY IN A BROADLAND RIVER.** Increasing levels of turbidity reported for parts of the Norfolk Broads over the last century have been attributed to algal growth. This paper demonstrates how the resuspension of bed sediments by a single moving boat is possible, and how the diurnal variation of boat traffic movement has distinct effects on patterns of suspended sediment concentration and hence turbidity. Control of boat speed and frequency thus has important implications for the management of turbidity levels in Broadland. (Author abstract) 22 refs.

**090548 THREE-DIMENSIONAL ANALYSIS OF BED DEFORMATION AND ITS APPLICATION TO**

**LOWER PART OF YODO RIVER.** During floods, scourings are often observed near levees and revetments, and they are grave menace to the safety of rivers. In order to forecast scouring, a three-dimensional analysis of bed deformation is investigated here with particular reference to the transverse sediment transport. The derived method is applied to the lower part of Yodo River. The present method cannot only explain the bed deformation during flood in 1982 but also give an instructive suggestion to design of phased river improvement. (Edited author abstract) 5 refs.

**090549 GESCHIEBEANALYSEN IN GEBIRGSFLUEESSEN: UMRECHNUNG UND VERGLEICH VON VERSCHIEDENEN ANALYSEVERFAHREN.** [Analysis of Sedimentary Bed Material in Mountain Rivers. Conversion and Comparison of Various Analytical Methods]. This report deals mainly with the problem of comparing and combining grain size distribution curves for the surface and lower layers of mountain river bed. A method is presented for converting the results of different analysis procedures to make them directly comparable with one another. Conversion coefficients determined in the laboratory, which account for the coarsening of the surface layer, are included in this method. Further, various procedures are presented for combining the results of different analyses, each of which covers only a part of the whole range of grain sizes. It is shown that line-by-number analysis, together with conversion and correction procedures and the prediction of the finer fractions from a Fuller distribution, gives an economical and reliable grain size distribution which also accurately represents the coarse components. (Edited author abstract) In German. 20 refs.

**090550 PROCESS-ORIENTED ESTIMATION OF SUSPENDED SEDIMENT CONCENTRATION.** Least squares regression and ARIMA models were developed from suspended sediment data for the Ausable River, Southern Ontario, Canada. A poor correlation between discharge and suspended sediment concentration results from the dynamics of the physical system, including seasonality, antecedent conditions, and hysteresis. Regression model results were significantly improved by the division of the data set into seasons and the addition of simple, but physically meaningful variables. Misleading improvements obtained from the regression of sediment load and discharge are discussed. ARIMA models provided accurate forecasts of sediment concentration on a real-time basis, but the rigorous data requirements limit their use in modeling suspended sediment concentrations in Canadian rivers. **090552 DETERMINATION AND SPECIATION OF COPPER AND LEAD IN SEDIMENTS OF A MEDITERRANEAN RIVER (RIVER TENES, CATALONIA, SPAIN).** Total concentrations of Cu and Pb and the speciation of these metals in sediments of the River Tenes are studied in order to establish the extent to which they are polluted and their capacity of remobilization. A standard reference material area (1556 mg kg<sup>-1</sup> Cu and 1555 mg kg<sup>-1</sup> Pb) in the last sampling site analyzed. For metal speciation, the sequential scheme of Tessier et al. was used. From the results obtained, it can be concluded that Cu content in non-residual fraction is bonded mainly to organic matter, whereas non-residual Pb is mainly associated to iron and manganese oxides. **090553 HEAVY METALS IN SEDIMENTS OF THE RIVER ECCLESBOURNE, DERBYSHIRE.** Sediments in the River Ecclesbourne are naturally contaminated with lead, zinc and cadmium from mineral veins at the head of the valley. Three riffles (shallow areas), near the mouth and source of the river and approximately midway between them, were examined in detail, with samples taken from upstream and downstream transects at each riffle. The median diameter of particles that passed through a sieve of 3.35 mm mesh was smaller in downstream transects, and the quartile skewness of particle size differed with both site and transect, although all samples had similar quartile deviations. Most particles were —light—, and the proportions of particles of three different ranges of densities varied with site, transect and size of particle. Metal concentrations decreased downstream and within sites concentrations varied with particle size and density by up to two orders of magnitude. Additional aspects of the study are discussed. (Edited author abstract) 12 refs.

## USSR

**090557 ESTIMATE OF LOSSES OF WATER RESOURCES TO EVAPORATION AND TRANSPIRATION IN THE ILI RIVER DELTA.** Based on existing calculation schemes and a summary of experimental investigations we have estimated the magnitudes of evaporation from an open water surface and different species of hydrophilous plants. The areas of bodies of water and wetlands are determined from aerial and satellite data obtained in 1958-1984. Annual losses in the delta to evaporation and transpiration are 3.3-4.0 km<sup>3</sup>. The decrease in losses because of the drying out of the delta as a result of construction of the Kapchagai HPP dam occurred after 1981, when the phase of replacement of superwetted areas by dry ones began. ## Widening

**090560 PENULTIMATE FLOOD ALLEVIATION CONTRACT AT ESHER.** Contract 11 covers the 1.1km length of river between the Hersham railway viaduct and Albany Bridge, with works also being carried out upstream of the bridge. Basically the contract is for the realignment and widening of the river between these points, and for the construction of flood walls and bunds upstream. Work is being done to lower the river and control its entry into the bridge with steel sheet piling. Beyond the bridge, the river will flow into an enlarged channel and where the improved and controlled hydraulics pass beneath the structure, protection is provided with gabion mattresses.

## RIVETING

**090561 VERBINDEN DURCH RADIALNIETEN.** [Joining by Radial Riveting]. Radial machine riveting was developed at the beginning of the seventies and is based on an advancement of the tumbling principle. It is used wherever high-quality rivet connections are required. Its successful application, however, is also documented by its manifold use in nonriveting technologies. Its advantages are perfect forming of the material, a low stress of the parts to be riveted, almost soundless and vibrationless working and the efficient technique used. This article deals with the equipment, some applications and the forming of the material. (Author abstract) In German.

Burkhalter, H. *F&M Feinwerktech Messtech* v 95 n 6 Sep-Oct 1987 p S136-S138, S140.

## Electromagnetic Field Effects

**090562 ANALYSIS OF RIVET DIE DESIGN IN ELECTROMAGNETIC RIVETING.** This paper presents the findings of a numerical and experimental study of the quality of 7050-T73 aluminum rivets formed by an extremely fast electromagnetic riveting process. It is found that without careful design of the rivet forming die large strains are produced which cause crack formation in the rivet heads. By the use of finite element and experimental techniques, it is shown that control of the radial component of the flow of materials in the rivet head is essential in avoiding crack formation. A rivet die design which is effective in producing high quality, crack free, rivets is proposed. (Author abstract) 12 refs.

## ROADBUILDING MACHINERY

## Accident Prevention

**090563 SAFETY MEASURES - WHILE WORKING WITH HOT MIX PLANTS AND ALLIED EQUIPMENTS.** Various types of road construction equipment are being used in road/bridge construction. Here we shall be dealing with safety measures requiring observation while working with hot mix plant and allied equipments, i.e., paver finisher, loaders and tippers, etc. Some of the most typical causes for accidents that have taken place at construction sites are: defective equipment devices and mechanized tools; violation of normal processes of operating the machines; and inadequate or no instructions to the drivers or operators, mechanics or fitter. The safety precautions mentioned are only a few. Many more safety precautions may have to be taken according to the working conditions prevailing at a particular site.

Gulati, D.R. *Indian Highw* v 15 n 7 Jul 1987 p 23-29.

**Costs** See PAVEMENTS—Repair.

## Maintenance

**090564 GUIDELINES FOR REUSABLE SPARE PARTS IN ROAD CONSTRUCTION.** Various road-making machineries such as hot mix plants (central type and mini type), pavers, loaders and rollers are commonly used for construction work, and some of this equipment is very expensive, involving equally expensive maintenance due to the exorbitant cost of spares fixed arbitrarily by the manufacturers. Under the reconditioning process, a worn-out member is reactivated by the process of heat-treatment, turning, truing, milling, welding, machining and retempering. A discussion is given on reconditioning the central hot mix plant, the paver finisher, the cylinder head, and the crankshaft.

Duraiswamy, D. (Highways Mechanical Circle, Tamil Nadu, India). *Indian Highw* v 15 n 11 Nov 1987 p 27-33.

**090565 COLD WEATHER TIPS FOR CONSTRUCTION EQUIPMENT.** Construction equipment needs special attention in cold weather to operate at optimum productivity. Moisture can cause costly and possibly irreversible damage to equipment at freezing temperatures. Several precautions should be taken before and during the winter to help ensure that equipment will operate properly in cold weather. This article reviews these precautions.

**Aggregates** See Also BITUMINOUS MATERIALS—Testing; PAVEMENTS—Performance; PAVEMENTS—Testing.

**090567 SPOT SHORTAGES WILL MEAN EXPANSION.** The article describes how several states in the U.S. have dealt with the problem of aggregate shortages. Among the alternatives, using recycled concrete and asphalt pavement has been greatly favored. On a recent project in Wyoming, recycling turned out to answer another problem - that of alkali-reactive aggregates causing premature structural failure. Few major changes have taken place recently in aggregate recycling equipment. One new development that shows promise for the future is the harmonic breaker, which uses vibration rather than impact to do its work.

**090568 SELBSTERHAERTENDE TRAGSCHICHTEN AUS HOCHOFENSCHLACKEN.** [Self-hardening Road Base Courses of Blast-Furnace Slag]. Blast-furnace slag and metallurgical sand are industrial by-products of great value to road construction if their hardening behavior and performance are duly taken into account. A road test program with varying formulations in small trafficked segments was to reveal the best application technique. The results are commented and interpreted by conclusions which now form part of a Preliminary Code of Practice on the subject. (Author abstract) 19 refs. In German.

Motz, Heribert (Forschungsgemeinschaft Eisenhuettenschlacken). *Str Tiefbau* v 41 n 4 Apr 1987 p 24, 26, 29-33.

**090569 QUANTITY OF FINES PRODUCED DURING CRUSHING, HANDLING, AND PLACEMENT OF ROADWAY AGGREGATES.** A three part test procedure was developed to determine the quantity of fines produced during crushing, handling, and placement of aggregates used as base course in roadway construction. The first test simulates crushing at the aggregate source. It involves processing an aggregate sample of specified gradation through a small laboratory jaw crusher. The second test simulates handling by agitating an aggregate sample of specified gradation at 10% moisture content for 20 min. The modified American Association of State Highway and Transportation Officials (AASHTO) compaction test is used to simulate placement. Following the conduct of each test in the procedure, the fines are measured by washing the aggregate over a 75-µm (No. 200) sieve. At the conclusion of the three part test procedure the fines produced during crushing, handling, and placement are determined by summing the fines determined from each test in the series. Additional aspects of the subject are discussed. (Edited author abstract) 5 refs.

Pintner, Robert M. (San Diego Soils Engineering Inc, San Diego, CA, USA); Vinson, Ted S.; Johnson, Eric G. *Geotech Test J* v 10 n 4 Dec 1987 p 165-172.

**090570 DIMETHYL SULFOXIDE (DMSO) ACCELERATED WEATHERING TEST FOR AGGREGATES.** A standard accelerated weathering test using dimethyl sulfoxide (DMSO) was developed to simulate the chemical degradation of basaltic rock. The final development of the standard test involved a study of the interaction of DMSO with clay standards and an investigation of the test condition parameters affecting an existing DMSO test procedure. The weighted loss reported under the existing test procedure (similar to the sodium sulfate soundness test) was affected by the aggregate particle size, specimen mass, immersion time, and container geometry. In the recommended standard DMSO accelerated weathering test, aggregates in the particle size range of 2.4 to 4.8 mm are immersed in a container of DMSO for a period of five days. Additional study results are discussed. (Edited author abstract) 18 refs.

**090571 DEGRADATION - UNBOUND AGGREGATES.** AGGREGATE degradation has been reported by many investigators to occur, in unbound layers of pavements, during construction and also during service life. The phenomenon of degradation has been recognised as one of the important factors affecting the performances of unbound aggregate in base, sub-base or in unpaved roads. Degradation is defined in this paper as the reduction in size of particles which occur during the process of laying and compaction and as a consequence of traffic action in association with weathering processes during pavement life. The work reported in this paper refers to a degradation study carried out in the laboratory in which different types of compaction, initial grading, material and size of compacting moulds were involved. 10 refs.

**090572 UNE REMARQUABLE INSTALLATION DE PREPARATION D'AGREGATS EN SUEDE.** [Outstanding Facility for the Preparation of Aggregates in Sweden]. The firm Skanska AB, which is the principal Swedish construction company, has just placed into service at Onnestad, near Kristianstad in Sweden, a new preparation plant for aggregate, which is quite remarkable in its design and its automation. This plant was constructed at the site of a quarry which the firm Skanska had operated for some 30 years and which supplies high-quality material for the construction of highways and the manufacture of concrete in the entire region. Design of this new plant, as well as supply of most equipment, were provided by the firm Svedala Arbra which is affiliated with the Boliden Allis group. Automation was also investigated and perfected by Svedala Arbra. Construction of this plant started in the fall of 1986, and the production startup was in August 1987. (Edited author abstract). **090573 ZEMENTGEBUNDENE MV-ASCHE IM STRASSENBAU.** [Cement-based Refuse Incineration Ashes for Road Construction]. In the Federal Republic of Germany there are 24 million tons of waste per year, a third of it is burned in 47 refuse incineration plants. A further number of 20 plants will be put in operation up to the year 1995. Then 14 million tons of refuse will be burned per year. From the year 1995 onward the amount of raw ashes from these plants will amount to 4 to 5 million tons per year. Large-scale examinations have proved that refuse incineration ashes set with cement cannot be leached out and thus do not endanger the environment. They can be used in road and street building. (Author abstract). 9 Refs. In German.

**090574 SLURRY SEAL MIX DESIGN.** The primary objective of this study was to devise a quantitative yet simple laboratory method for designing emulsified bitumen slurry seal coats. A laboratory design procedure for slurry seal, the New California Test 355 (NCT355) was studied. Some modifications are suggested following experimentation. This paper presents the results of a laboratory evaluation of the mix design and a field verification of the laboratory design. The laboratory and field work were preceded by a thorough review of NCT355 and of other pertinent literature. During the laboratory phase, the test method was rigorously scrutinized for possible modification and simplification in order to make it more convenient without sacrificing accuracy and reliability. The field verification phase is also discussed. (Edited author abstract) 7 refs.

**090576 TRUTH ABOUT REMIXING ASPHALT.** The remixing process is not right for every road, but where it can be used, it can account for significant cost reductions. The reduced cost stems from the fact that one machine picks up the old asphalt, recycles it, and lays the material back down on the road. The largest savings come when the process is applied to a badly rutted road where grinding and two courses are needed. On less severe projects, the savings are lower. This article discusses the remixing process and equipment, applications, and remixing work in Maryland.

Anon. *Better Roads* v 57 n 12 Dec 1987 p 18-20.

**090577 BITUMEN EMULSIONS FOR ROAD CONSTRUCTION AND MAINTENANCE.** Today, we have a range of different grades and types of emulsions, along with appropriate construction equipment, which can be used for most road construction and maintenance jobs. The series of cationic bitumen emulsifiers developed recently are significant for highway construction. When the cationic emulsion comes into contact with the aggregate, an ion-absorption occurs between the positively-ionized particles of cationic bitumen emulsion and negatively-ionized aggregates, even when the aggregates are in a damp condition. This improved cohesion between the bitumen and aggregates permit use of cationic emulsions even in wet and relatively cold weather conditions and permit the road to be opened to traffic soon after paving. The use of bitumen emulsions is also energy-saving and pollution-reducing.

**090580 ADDITIVES FOR BITUMEN IN ROAD CONSTRUCTION.** In this paper an attempt has been made to document the effects of some additives on

conventional properties of bitumen. These properties are penetration value, softening point, ductility, and stripping value. The additives are derived from plants. Various tests have been conducted on a mixture of 80/100 grade bitumen and different types and percentages of additives. A detailed investigation has been carried out on five additives which have been code-named A, G, S, T, and W. The test results indicate a definite trend in the variation of the conventional physical properties of bitumen for Additives A, G, and W and a spectrum of values with finite variation in the conventional properties for Additives S and T. (Edited author abstract). 5 Refs.

**Deformation**

**090581 EVA MODIFIED BINDERS.** In the majority of road situations conventional bituminous materials give satisfactory performance. However, for certain special applications and sites where traffic is extremely heavy improved materials are required. Copolymers of Ethylene and Vinyl Acetate (EVA) offer an effective means of modifying the rheological properties of conventional penetration grade bitumens, thus enabling the production of high quality materials with in particular improved resistance to deformation and handling properties, for use on heavily trafficked roads and motorways and for difficult working conditions. 8 refs.

**Fly Ash**

**090582 LEACHABILITY OF LIGNITE FLY ASH ENHANCED ROAD BASE.** The abundance of fly ash along with its self-hardening properties led the Louisiana Department of Transportation and Development (LA DOTD) to use fly ash as a soil stabilizer for road bases. During this study, a total of three samples, a 30 percent lignite fly ash/soil mixture, lignite fly ash, and soil, were leached following the EPA multiple extraction procedure and analyzed by Inductively Coupled Argon Plasma spectrometry (ICAP). Results indicate that little change in leachate quality of lignite fly ash was caused by the soil stabilization process. The insignificant change is attributed to the low cation exchange capacity of the soil. ICAP analysis revealed that heavy metal concentrations were within RCRA and Public Drinking Water standards. Additional study results are discussed. (Edited author abstract) 11 refs.

**090586 SPECIAL MATERIALS - THEIR USE AND APPRAISAL.** Special materials are now used in many situations in highway works. This paper shows how the properties required from these materials will vary with their usage, and the importance of defining combinations of properties in a way which will show those of greatest significance. The use of response groups for this purpose is demonstrated. Testing must be specified so that both the right test and the right test conditions are defined, as these are of greater importance when using special materials. Case histories are used to show how particular situations require specific material properties. (Author abstract) 4 refs.

**Plastics**

**090587 DEVELOPMENT OF A SECOND GENERATION OF PLASTICIZED SULFUR (SULPHLEX) BINDER.** Two second-generation plasticized sulfur formulations were identified as possessing low-temperature engineering properties that are much improved over the first-generation formulations. The J-integral, a measure of the energy required to induce crack growth, was found to be an excellent and sensitive parameter by which to evaluate the low-temperature fracture susceptibility of the plasticized sulfur binders. A strong relationship was found between the critical energy required to indicate crack growth,  $J_{IC}$  and the glass transition temperature of the plasticized sulfur binders. The second-generation binders presented are evaluated based on creep compliance, controlled stress and controlled displacement fatigue, glass transition temperature, and the  $J_{IC}$ . **Recycling** See Also ROADS AND STREETS.

**090588 COLD MIX RECYCLING - THE CLIENT'S VIEW.** Cold mix recycling of old roads is not a new process in the UK. Back in the 1930s some existing pavements were improved by the in situ mixing of bitumen emulsions following scarification and reshaping of the old surface. This 'Retread' process, little changed except for improvements in machinery, is still a viable alternative for roads where no overall structural improvement is required but correction of ruts, crack or pot-holes is necessary. With in situ recycling, 100% of the existing road pavement is re-used and the potential quality of this 'horizontal quarry' of material has to be assessed. Cold-mix bituminous material is about 80% as efficient as hot mix material in its load spreading capabilities. The reasons for this are partly due to the inability to fully compact materials on a yielding foundation, partly due to the difficulty of ensuring an intimate contact between bitumen an intimate contact between bitumen and cold damp materials.

## Standards

**090589 CONCEPTUAL FRAMEWORK FOR THE DEVELOPMENT OF PERFORMANCE-RELATED MATERIALS AND CONSTRUCTION SPECIFICATIONS.** It is assumed that the conceptual framework for specifications development includes eight sets of relationships among the process variables and nine sets of inputs or outputs for the relationships. Independent variables are selected that have predictable effects on performance-related output variables. From these independent variables, variables (EPF) appearing explicitly in prediction functions are selected and subdivided into traffic factors, environmental factors, and pavement structure factors. General forms of prediction equations for stress and distress, stress-load equivalence relationships, traffic prediction relationships, relationships among materials and construction (M&C) specification factors, and performance-cost relationships are presented. Pavement design criteria and M&C specification factors are added as the initial conditions for the definition of a pavement design for a given pavement requirement. (Edited author abstract). 7 refs.

**090591 DEVELOPMENT OF SPRAY-REDUCING MACADAM ROAD SURFACINGS IN THE UNITED KINGDOM, 1967-1987.** The evolution of pervious macadam has been primarily the result of a number of road trials that have led to specification trials by the Department of Transport. The resulting specification for pervious macadam is included in the latest revision of British Standard 4987. The material can be expected to have effective spray-reducing properties for 3 years for a traffic flow of 7,000 commercial vehicles per day (cvd) per lane or for 6 years for 2,500 cvd. To improve the long-term durability of the material and its economic viability, a road trial was started in 1984 to study the performance of pervious macadams with polymer-modified binders. ## Waste Utilization

**090592 ERFAHRUNGEN BEIM EINSATZ VON MUELLVERBRENNUNGSASCHEN IM TIEF- UND STRASSENBAU UNTER BESONDERER BE RUECKSICHTIGUNG DER VERWENDUNG IN BEREICHEN MIT UNTERIRDISCHEN VERSOR GUNGSLEITUNGEN.** [Experience with the Application of Refuse Incineration Ash in Pipeline and Road Construction, Especially in Areas with Underground Water Pipeline Networks]. About 2 Mt p.a. of solid waste are produced annually in the Federal Republic of Germany by household refuse incineration. About 70 to 80% of it, above all ash, can be utilized in a prepared and controlled state in pipeline and road construction for frost and carrier layers, soil strengthening or agricultural and forestry purposes. The road construction requirements are contained in a publication of the German Research Association for Road Construction and Transportation (FGSV) published in 1986. In the water protection zones 1-3 refuse ash is not permitted. The corrosion risk for pipelines with external insulation coatings is equal to zero. Pipelines that lay in refuse ash since 1975 have shown no damage. Pipes have to be protected from immediate contact with refuse ash by a layer of sand or soil at least 80 cm thick. (Translated author abstract) In German.

**090596 LOCAL ROADS AND STREETS INTO THE NEXT CENTURY.** In examining the role of roads and streets into the next century, it is not enough to merely study the likely changes in road and street technology. A wider view is needed as roads and streets supply a means that the community uses to service a set of broader needs - the need to travel, to trade, to socialise, to produce and to consume. It is only after exploring these more basic needs that we will be able to make sensible statements about the future of roads and streets. In addition to needs, the paper discusses motor transportation in general, roads and streets, and safety. 20 refs.

**Accident Prevention** See Also URBAN PLANNING—Transportation.

**090597 ROAD SAFETY - SUCCESS AND FAILURE IN JAPAN.** The Japanese success in the 1970s in reducing its traffic accidents by 50% was brought about mainly by traffic engineering measures to improve the road and roadside environment. In the 1980s, however, those measures that were effective in the decade before are approaching their saturation levels in terms of both the number of installations and the extent to which they could prevent accidents; hence they become less and less effective. Stress should now be placed on a new policy to improve driver quality. To realize this purpose revision of driver education, traffic regulations, and the way in which traffic regulations are enforced is inevitable. In particular, reformation of pre-license driver education is important. Special attention should be paid to the education of young drivers because the majority of new drivers are young drivers and they have a remarkably high accident rate. 8 refs.

Koshi, M. *ITE J* v 57 n 9 Sep 1987 p 33-41.

**090598 TRAINING CHILDREN IN ROAD CROSSING SKILLS USING A ROADSIDE SIMULATION.** Five-year-old children were trained in road-crossing skill using a new method which allows them to act safely in relation to vehicles on a normal road. The children learned to time their crossings of a 'pretend road' as if the vehicles were on this, rather than on the adjacent road. A previous study, using a single lane of traffic, showed that many children performed well in this simulation with minimal instruction, but that five-year-olds were generally less

proficient than older children. In the present study, the method was extended to the more realistic case of two-way traffic, and training programs for five-year-olds were assessed. In addition, the performances of adults in the two-way pretend task and in actual crossing the road were compared; the results confirmed the validity of the simulation. After a few sessions of guided practice, the children's efficiency in making use of gaps by setting off promptly after a vehicle had passed improved markedly; in single-lane crossing they reached almost adult standard. (Edited author abstract) 16 refs.

Young, David S. (Univ of Edinburgh, Edinburgh, Scotl); Lee, David N. *Accid Anal Prev* v 19 n 5 Oct 1987 p 327-341.

**090599 CURRENT STATE OF ROAD SAFETY EDUCATION IN PRIMARY AND MIDDLE SCHOOLS.** In June 1984 a survey was conducted to provide information about the current state of road safety education in primary and middle schools. Over 90 per cent of the schools claimed to have been teaching some form of road safety education. Outside specialists (mostly the police and road safety officers) had made a substantial contribution to the subject by giving talks in 83 per cent of the schools. The input from teachers was, however, largely incidental. The limited use made by teachers of road safety curriculum materials, their limited preparation to teach road safety education and the lack of a well developed organization structure for road safety education within primary and middle schools were identified as factors requiring immediate attention if the provision of road safety is to be further improved for schoolchildren aged 5-13. (Edited author abstract) 13 refs.

**090600 EASING THE IMPACT OF ROADSIDE CRASHES.** A priority of the Federal Highway Administration (FHWA) has long been to improve road-building technology and the safety of highway users. Because full-scale crash tests can reliably duplicate actual collisions, they are the traditional standard for developing and evaluating roadside safety hardware. However, in order to reduce costs and improve the repeatability of test results, alternative test methods have been developed over the years. This paper discusses tests conducted at the Federal Outdoor Impact Laboratory, where a reusable test vehicle and small cars are being run head-on and sideways into sign posts, light poles, and guard rails in an effort to make roadsides safer.

**090601 OVERHEIGHT-VEHICLE DETECTOR SYSTEM.** Lothian Region's Transportation Committee instructed their Department of Highways to investigate the possibility of installing a system to reduce the incidence of overheight vehicles colliding with bridges at two sites. Despite the demanding requirements, a company was discovered with the necessary optical, electronic and mechanical expertise to construct and install the equipment. The system is based on the use of two solid-state light sources transmitting invisible beams of infrared light from a pole on one side of the road to two detectors mounted on a pole on the opposite side of the road. When the system detects the passage of an overheight vehicle, it promptly activates a fiber-optic vehicle diversion sign. 3 refs.

**090602 ENGINEERING ANSWERS.** Cambridge-shire County Council aims, by the year 2000, to achieve a reduction in casualties of 10% by giving higher priority to major road schemes which will cut accidents, and by increasing the money spent on low-cost accident remedial schemes. An outline of the main remedial engineering techniques includes: a black site will be identified on a

slightly different basis by each county in the light of the severity of accidents in the county and the resources available; route action is the application of accident prevention measures along a particular route; area action usually attacks the accident problems of part of a town or city by a combination of engineering measures, education and enforcement. There have been spectacular results in many counties using these techniques. Cambridgeshire, over the last five years, has achieved more than a 200% return on total capital investment and the cut in the number of accidents on most sites is significant.

Oldridge, Brian (Cambridgeshire CC, Engl). *Surveyor (Sutton Engl)* v 169 n 4978 Jan 21 1988 p 16.

**090603 EDUCATION, ENFORCEMENT, ENGINEERING.** Road Safety. The Next Steps summarizes the findings of an interdepartmental review of road safety policy. It also promotes the redirection of resources to be concentrated on the most cost-effective policies in value for money terms, at the expense of policies of questionable value in economic terms. The report proposes the concentration of resources on three prime policies, namely curriculum studies, low cost engineering schemes and research, with little value being placed on road user education/training, campaigns or enforcement. The author discusses the report and suggests three ways that the government can improve its road safety: education; enforcement; engineering.

Aylott, Roy (City of London Corp, Engl). *Surveyor (Sutton Engl)* v 169 n 4978 Jan 21 1988 p 18-19.

**090604 RIDE SAFETY OF ROADS VEHICLES.** As vehicles ride over rough roads, they respond dynamically and inadequate road holding may arise. This paper examines the ride safety of an articulated vehicle over irregular roads through an analytical study. The vehicle's responses to road surface undulations are studied using (a) spectral density approach, and (b) statistical linearization approach. The first approach is reviewed and applied to a linearized vehicle model to obtain the dynamic wheel loads. The second approach is presented and used to deal with the various nonlinearities in vehicle suspension systems. The results of the classically linearized system are presented and conclusions are drawn as to the applicability of both approaches. (Edited author abstract). 15 Refs.

**090606 ANALYSIS OF THE HAZARD INVOLVED IN TURNING OFF FROM THE OUTSIDE OF LARGE RADIUS CURVED ROADS ACROSS THE PATH OF ON-COMING TRAFFIC.** One of the most common types of traffic accidents involves vehicles turning right from a major road across the path of on-coming traffic. They usually result from misjudgement by the turning driver of the available time gap. The situation is particularly hazardous if the turn-off is located on a large radius curved section of the major road, when the turning driver is on the outer side of the curvature. This situation is analysed in this note. The derivation of a formula for the calculation of the distortion in the estimated speed of the on-coming traffic is also presented. 2 refs.

**090607 NEW PARLIAMENT HOUSE ACCESS ROADS.** Provision of appropriate access to New Parliament House involved the resolution of sometimes conflicting requirements, including consideration of the existing topography and road networks, observance of good traffic engineering practice, requirements of existing and projected traffic and the existing infrastructure. The ceremonial approach to the House is provided by the Land Axis which links the Parliamentary Triangle with the Forecourt of the new Parliament House. This link is both visual and physical and is provided by two roads and a continuity of landscape between the two buildings. The Parliament House Access Road structures have been designed to provide the initial welcoming gesture to all visitors. They are complementary in both principle and detail to the architecture and landscape of Parliament House. Concrete is the predominant material and the structures exhibit high quality in situ and precast concrete finishes.

**Computer Aided Design**

**090608 CORPS OF ENGINEERS LOW-VOLUME ROAD DESIGN.** The U.S. Army Corps of Engineers' pavement design procedures are particularly appropriate for low-volume road applications because they were developed from traffic tests using relatively low traffic volumes and thin pavement sections on low-strength subgrades. The flexible pavement criteria are most appropriate for thin asphalt concrete pavements in granular base courses and subbases. However, development of roller-compacted concrete pavement construction has made rigid low-volume pavements feasible in many situations, and the corps design method is capable of addressing roller-compacted concrete pavement characteristics. These design procedures, published in Army technical manuals, have also been computerized. (Edited author abstract). 4 Refs.

**090609 ARTERIAL ROAD FUNDING FOR SOUTHEASTERN JEFFERSON COUNTY: EQUITY BASED ON TRAFFIC IMPACT.** Rapid development has resulted in a sudden deterioration of traffic conditions in southeastern Jefferson County, Colorado. This has led to an intensive effort to develop a funding and construction program to alleviate the deficiencies and provide for future needs. Traffic projections were used to size the needed roadway system and derive improvement costs, which were apportioned to each land use category on the basis of traffic generation. This apportionment became the main parameter for establishing a 20-year funding plan

made up of three revenue sources: property tax, sales tax, and traffic impact fees on a 1/3, 1/3, 1/3 basis. (Edited author abstract) 1 ref.

**090612 IMPRESSIONS OF A STUDY TOUR TO THE USSR ON ROAD CONSTRUCTION AND MAINTENANCE.** A two-week seminar on construction and maintenance of roads in wet, marshy and arid areas in the USSR was organized in August 1987 by the United Nations Economic and Social Commission for Asia and the Pacific (ESCAP). It was attended by the author as a delegate from India along with 13 other delegates from 13 other Asian and Pacific countries like China, Japan, Thailand, Malaysia, Afghanistan, Burma, Sri Lanka, Bangladesh, Philippines and a few delegates from USSR. Some of the general impressions formed on the basis of information gathered during the Seminar are given. Subjects covered include roads in wet and marshy areas, embankments on soft soils, roads in arid and desert areas, soil stabilization, practices in other countries, drainage, and others.

**090613 THOMAS ROY AND HIS 'REMARKS ON ROAD-MAKING' (1841).** Thomas Roy was a civil engineer and geologist who lived in Toronto from 1834 to 1842; he was probably Canada's first geotechnical engineer. In 1835 he carried out the survey for what would have been Canada's first railway if it had then been constructed. He acted as City Engineer for the fledgling city. Nothing is yet known of his life before 1834 but the search continues. In 1837 he presented to the Geological Society of London a paper on the former, raised water levels of the Great Lakes, based on his field observations while surveying. In 1841 he wrote and had published a remarkable little book on road making, in some ways far ahead of its time; significant extracts are presented. (Author abstract) 10 refs.

**090614 METHODS THAT CAN REDUCE WORK ZONE FATALITIES.** Flaggers and construction workers, as well as the driving public, are endangered in highway work zones. Studies show that accident rates climb during construction. Four techniques to improve the effectiveness of speed zoning in construction areas on multi-lane freeways were recently studied. The procedures studied included: Flagging using procedures of the Manual on Uniform Traffic Control Devices (MUTCD). Use of the MUTCD flagging procedure, plus the flagger using

a free hand to point at a nearby speed-limit sign. Use of a marked police car with cruiser lights and radar active. Use of a uniformed police officer standing to control traffic. This article discusses the study and its results.

Anon. *Better Roads* v 58 n 4 Apr 1988 p 33-34, 38, 40.

**090615 OPTIMIZATION OF ENGINEERING PREPARATION IN THE ROAD CONSTRUCTION PROCESS.** Results are presented of the development of economic-mathematical models, methods, and algorithms for the solution of optimization problems in the distribution of soil masses and in the outline of the design profile of a longitudinal roadbed. These developments are based on the principles of system optimization. They ensure the automation of the technology of the process of making design decisions by adapting the problem to the requirements of the person making the decision. Such an approach allows one, when correcting projects, to take into account production, social, economic and other factors, to evaluate alternatives under conditions of indeterminacy, as well as to increase the timeliness of design decision-making. 4 Refs.

## Database Systems

**090616 INROADS: A NEW DATABASE FOR ROADS AND TRANSPORT.** A computer-based library catalog, called ROAD, using the same format as Australian Road Research Documentation or ARRD, was developed to handle new additions to the ARRB library from January 1984. The catalog was not publicly available; however, State Road Authority libraries were provided with passwords for this file. In response to the comments of ARRB library users, the feasibility of combining the ARRD and ROAD databases was explored, with the result that a new combined database called INROADS has just been mounted on CSIRO's AUSTRALIS network. The new file is available publicly to all users of AUSTRALIS and it should prove a boon to anyone interested in roads information in Australia.

Price, R. (Australian Road Research Board). *Aust Road Res* v 17 n 2 Jun 1987 p 137-140.

**Degradation** See Also HIGHWAY SYSTEMS—Evaluation.

**090617 MANHOLE COVER DETERIORATION DIAGNOSIS TECHNIQUE.** This paper describes a technique for diagnosing manhole cover deterioration. Manhole covers installed on road surfaces suffer damage such as internal cracking and enlargement due to the repeated buffeting of vehicular traffic. The deterioration process in cast iron was investigated and the speed of crack growth was determined theoretically. The extent of cover damage was evaluated quantitatively by analyzing the free vibration characteristics after striking the cover with a hammer. These investigations have led to the development of a handy tester which is capable of measuring the life span of a cover in about 5 minutes. (Author abstract) 10 refs.

**090621 NEED FOR ADEQUATE INTERSECTION SIGHT DISTANCE IN ROADWAY DESIGN.** The design of roadway improvements or new facilities normally focuses much attention on the selection of design speed, which controls the horizontal and vertical alignment. Design speed is one of the main criteria used to attempt to achieve uniform speeds with minimum variations and to realize consistent and safe operations on roadways. Design speed establishes maximum degree of curvature or minimum radius for horizontal curves and suitable length of vertical curves to provide safe stopping sight distance in the case of emergencies. Thus it is important that adequate sight distance be provided at intersections of streets and driveways with major roadways. Proper sight distance would improve safety and result in better operating conditions. 2 Refs.

## Developing Countries

**090622 VIEW OF ROAD MAINTENANCE ECONOMICS, POLICY AND MANAGEMENT IN DEVELOPING COUNTRIES.** Work that has been carried out at the Transport and Road Research Laboratory of the United Kingdom in the field of road maintenance in developing countries is reviewed under the headings of economics and policy, project implementation, and management. Numerical examples are given to illustrate the economic benefits of road maintenance, and some of the reasons for the poor conditions of road networks in developing countries are discussed. Different approaches to carrying out maintenance are described, including a discussion of equipment and labor-based methods, and of using contractors. Recommendations are made on priorities for budgeting. Maintenance management systems are described in terms of their objectives and their component steps, and the recommendation is made that maintenance frequencies should be determined on an economic basis using whole-life costs. Examples of the use of such methodology in the management of unpaved roads are given. The need for condition measurement surveys to determine maintenance needs for paved roads is described and different methods of rapid assessment are discussed. 62 refs.

**090623 STORM DRAINS REQUIRE CORROSION-RESISTANT MATERIALS.** A recently completed 4.8 million dollar project contracted by the State Highway Administration of Maryland involved constructing a 17,500-ft-long median strip to divide the six lanes of State Route 528 in Ocean City. This article discusses the storm drain installation for the highway. Selection of corrosion-resistant materials is reviewed.

Anon. *Public Works* v 119 n 8 Jul 1988 76p.

## Economics

**090624 ECONOMIC ARGUMENTS ON TOLL ROADS.** From the economic point of view, tolling is an instrument that can be uniquely suited to the collection of efficient road use prices. It is important to ensure that effects on the economy at large, not only on the toll agency, are included in toll road analysis. This is not generally done and is the reason for this paper. There are, however, a number of conditions under which tolling may be appropriate (i.e., not worsen resource allocation or even improve it over untolled roads despite higher costs inevitably entailed in tolling with current technologies). Examples of results from tolling in two developing countries are provided. Only tolling of interurban roads is discussed. (Edited author abstract)

**Embankments** See Also EMBANKMENTS—Protection; LAND RECLAMATION—Revegetation; RAILROAD PLANT AND STRUCTURES—Track.

**090625 WESTBOUND EMBANKMENT PRELOAD ON RAINIER AVENUE, SEATTLE, WASHINGTON.** Fifty-foot-high approach embankments recently completed for a bridge crossing of Rainier Avenue in downtown Seattle required preloading of compressible lacustrine clay sediments as much as 50 ft thick below the abutment areas. This paper presents the results of engineering analyses and recommendations for very complex surcharge fill requirements. Vertical prefabricated drains were used in the preload to accelerate settlement and an unprecedented 55-ft-high soil-reinforced wall was used to limit the extent of the fill and thereby prevent damage to existing utilities and adjacent structures. The instrumentation program used to measure the settlement response is discussed, and the variation in magnitude and time rate of settlement measured across the site is summarized. (Edited author abstract) 6 refs.

**090626 USE OF WOOD FIBER IN LIGHT-WEIGHT EMBANKMENTS FOR NORTHERN APPLICATIONS.** The application of wood fibers to road-way embankments may provide a convenient solution to the most perplexing problem northern engineers face. Prior case studies have yielded excellent results in the State of Washington when used for soft soil conditions. Much work needs to be done in the areas of further defining both wood fiber and permafrost engineering properties. Important values need to be established for the viscoelastic properties of permafrost as well as engineering properties of the wood fibers, such as compressibility values as in clays, and reliable values for the modulus of elasticities of various fiber sizes and species. 6 refs.

McMahon, Robert J. (Univ of Utah, Salt Lake City, UT, USA). *North Eng* v 19 n 3-4 Fall-Winter 1987 p 35-39.

## Environmental Impact

**090627 ENVIRONMENTAL HAZARDS AND IMBALANCE OF ECO-SYSTEM DUE TO ROAD DEVELOPMENT.** The theme of this article represents the environmental and ecological changes that a region will experience due to construction of new road. The specific region (in India) discussed has already undergone environmental degradation by construction of several major projects close to the alignment of the new road. These projects have not only contributed to environmental degradation and imbalance in ecosystems but displaced local population causing them to shift laterally towards the new alignment thereby overcrowding the area and effecting drastic changes in the land use pattern.

Panda, Jagdish (N.H. & Project Circle, Angul, India). *Indian Highw* v 15 n 6 Jun 1987 p 26-33.

**090628 STUDY ON IMPACT OF ROADS ON VARIOUS SECTORS OF DEVELOPMENT IN TAMIL NADU.** In this paper, the impact analysis has been carried out through the use of factor analysis and regression analysis techniques. A host of development indicators relating to different sectors of the economy has been developed and measured for each district in Tamil Nadu. The values of development indicators have been used in factor analysis and then the values of factors are used in regression analysis. The analysis has clearly established that roads have a wide ranging impact on all the sectors of economy. (Author abstract)

Srinivasan, N.S. (Natl Transportation Planning & Research Cent, Trivandrum, India); Herur, Arun; Chand, Mahesh. *J Inst Eng India Part CI* v 68 n 2 Sep 1987 p 102-109.

**090629 EVALUATION TECHNIQUE FOR SOCIAL AND ENVIRONMENTAL ASSESSMENT OF ROADING PROPOSALS.** This paper describes the form of analyses used recently in Christchurch to assess the merits of proposed road works. In particular, it describes the method developed to assess the social and environmental effects of traffic planning. The results of the environmental and social assessment are discussed and some modification of the approach is suggested. In the past, more deterministic methods of assessment such as improvement in traffic systems measures and/or benefit cost analysis have alone been used to justify road works. With relatively less road expenditure being used to add to the urban network, wider examination of the effects of such expenditure is to be encouraged. (Author abstract)

Wood, D. Ritchie (Canterbury United Council). *Trans Inst Prof Eng NZ Civ Eng Sect* v 14 n 3 Nov 1987 p 141-146.

## Evaluation

**090630 RATING UNSURFACED ROADS.** About two-thirds of all highways in the United States are unsurfaced or lightly surfaced low-volume roads. To help local highway agencies manage the maintenance of these roads, a system for rating each section of road has been developed to indicate how badly that section needs repair and to identify problem areas. An unsurfaced road is any road that does not have portland cement concrete, asphalt concrete, or other surface treatment. Some agencies consider gravel to be a surfacing material; for the purposes of this article a gravel road is an unsurfaced road. The method for rating the condition of unsurfaced roads has three steps: 1) dividing the road network into sections; 2) inspecting the sections and identifying problems; and 3) calculating ratings that indicate the condition for each section.

**Failure** See Also FLOOD CONTROL; MOTOR TRUCKS—Australia.

**090631 SEALING OF CRACKS IN BITUMINOUS**

**SURFACE WITH RUBBERIZED BITUMEN.** All kinds of failure of roads render the riding quality of the road poorer and also reduce its future life and load carrying capacity. The riding quality of a cracked bituminous surface is much poorer as compared to its original quality without any cracks when laid. Besides, the cracks make the surface ugly. Cracks may range from simple hair cracks appearing on the surface which may not affect the riding quality of the road much, too wide cracks penetrating through the bituminous layer, and if not taken care, may spoil the surfacing and the road completely in due course of time. Sealing of cracks in bituminous surface by rubberized bitumen before laying fresh layers of bituminous macadam and/or dense asphaltic concrete, gives satisfactory results. This article is based on a practical example where rubberized bitumen for sealing cracks in bituminous surface, has actually been used and is behaving satisfactorily. 3 refs.

Sinha, B.N. (PWD Delhi Admn, New Delhi, India). *J Indian Roads Congr* v 48 n 1 Aug 1987 p 177-185.

**090632 THEORETICAL ROAD DAMAGE DUE TO DYNAMIC TYRE FORCES OF HEAVY VEHICLES. PART 2: SIMULATED DAMAGE CAUSED BY A TANDEM-AXLE VEHICLE.** The literature relating to road surface failure and design is briefly reviewed and the conventional methods for assessing the road damaging effects of dynamic tire forces are examined. A new time domain technique for analyzing dynamic tire forces and four associated road damage criteria are presented. The force criteria are used to examine the road damaging characteristics of a simple tandem-axle vehicle model for a range of speed and road roughness conditions. It is concluded that for the proposed criteria, the theoretical service life of road surfaces that are prone to fatigue failure may be reduced significantly by the dynamic component of wheel forces. The damage done to approximately five per cent of the road surface area during the passage of a theoretical model vehicle at typical highway speeds may be increased by as much as four times. (Edited author abstract) 32 refs.

## Foundations

**090633 IMPROVED ROADBASE MACADAMS: ROAD TRIALS AND DESIGN CONSIDERATIONS.** Previous pilot-scale investigations have shown that improved macadams with a larger grade of binder and more filler than normal dense bitumen macadam have considerable potential and full-scale trials should take place. These materials for use in roadbase construction have now been evaluated in five motorway and other trunk road contracts. Analysis of the production process showed that it might cost up to 10 percent more, but its superior load spreading ability allows a thinner depth of construction to be specified and the overall cost saving is likely to be at least 12 percent. There are situations where additional filler is not readily available or where its use leads to longer mixing times and a significant reduction in productivity of the mixing plant: the additional filler may then be omitted and the resultant material will still be more cost effective than normal dense bitumen macadam. Analysis of the structural properties of material taken from the five reconstruction sites provided a basis for design curves relating thickness of construction to cumulative traffic loading over the design life of the pavement. (Author abstract) 7 refs.

Nunn, M.E.; Rant, C.J.; Schoepe, B. *Res Rep Transp Road Res Lab* 132 1987 15p.

**090634 PROOF TESTING OF ROAD FOUNDATIONS.** Publication of TRRL LR 1132 in 1984 introduced into the UK design methods the concept of relating pavement structural design to the resilient properties of

road foundation constituent materials. Using these methods the road foundation itself is designed to meet construction haul road requirements with the provision that the support to the overlying pavement layers is at least equivalent to 225 mm Type 1 sub-base above a subgrade of 5% CBR. The report stated the desirability of proof-testing the road foundation to establish, prior to placing road bases, that the required level of support was available. This support has been defined in terms of dynamic or resilient moduli of the layers forming the pavement foundation. For granular materials in particular, the dynamic moduli and the static moduli are stress-dependent. 18 refs.

**Frost Effect** See Also CONCRETE—Disintegration; PAVEMENTS—Testing.

**090635 POLYSTYRENE FORM AS A FROST PROTECTION MEASURE ON NATIONAL ROADS IN SWEDEN.** In the specifications of the National Road Administration in 1976, the extruded polystyrene skin-board, type HI 50 from the Dow Chemical Company, was recommended for use in an insulated road base. For skid resistance, the depth of insulation was changed from 50 cm, according to the 1976 specifications, to 40 cm below road surface in the specifications of 1984. This change was based on experience from the Swedish Road and Traffic Research Institute test field. A new procedure is being developed making it possible to calculate the frost heave when the frost penetrates below the base into underlying frost-susceptible soils. The procedure is based on determination of the frost heave properties of soils by a direct freezing test. This make it possible to optimize the frost-protective base construction in relation to local climatic, geological, and hydrological conditions at the site. (Edited author abstract). 5 Refs.

## Guard Rails

**090636 PERFORMANCE OF LONGITUDINAL TRAFFIC BARRIERS.** This report presents findings and conclusions from the evaluation of an array of longitudinal traffic barriers. The barriers were evaluated according to the NCHRP Report 230 criteria. Special emphasis was given to barrier systems currently in use in large numbers. Existing crash test performance of longitudinal barrier systems was reviewed for compliance with NCHRP Report 230. Based on this review a matrix of five guardrail, two median barrier, and four bridge rail systems was evaluated with full-scale crash tests for occupant risk with 1,800-lb (820-kg) sedans (test 12 in Table 3 of NCHRP Report 230). The results were evaluated using the recommended values of NCHRP Report 230 to which all systems were essentially in compliance. Further evaluation of five guardrail and one median barrier systems was performed with an 1,800-lb (820-kg) sedan impacting at 60 mph (95 km/h) and a 20-deg angle (test S13 of NCHRP Report 230). The purpose of these tests was to provide further insight into the performance of the barrier systems. (Edited author abstract) 20 refs.

**090637 CUSHIONING THE BLOW BRUMMIE STYLE.** The guard rail energy absorbing terminal (GREAT) crash cushion system in Birmingham has saved lives by protecting occupants in collisions with rigid objects. The crash cushion solves the problem of protecting narrow rigid objects by a series of unique design features. The corrugated side panels and backups form a torsionally stiff box which resists lifting and twisting under impact. Penetration of the vehicle's passenger cell by the side panels is prevented by backup systems, and in some cases a steel cable anchors the system to the ground. Redirection in side impacts is provided by the inherently

stiff structure, and by chains attached to the ground.

Proctor, Steve (Birmingham City Engineer's Dep, Birmingham, Engl); Greaves, Des; Beresford, Tony; Bowling, John. *Surveyor (Sutton Engl)* v 169 n 4978 Jan 21 1988 p 20-22.

## Ice Problems

**090638 CHEMISTRY OF DEICING ROADS: PENETRATING ICE.** Experimental measurements of the rates at which sodium chloride, calcium chloride, urea, and calcium magnesium acetate (CMA) penetrate ice are consistent with a theory developed to predict this rate. These measurements and theory complement earlier studies of the rate at which ice can be deboned from road pavement. The mass transfer coefficients found from the penetration measurements are similar to those found from spinning ice disks, but are much less than those found for debonding. Possible reasons for this discrepancy and the steps that limit road deicing are discussed. (Author abstract) 15 refs.

## India

**090639 NEW THINKING ON PRIVATE-SECTOR TOLL ROADS IN INDIA: RATIONALE AND ISSUES.** India has the fourth longest road network (1.7 million km) in the world (Table 1), about 0.8 million km of which are paved, but the unfinished tasks are stupendous: merely to connect by road all villages of 500 or more people by the year 2001 and to raise road density to 0.82 km/km<sup>2</sup> from the present 0.46 km/km<sup>2</sup>, the length of the road network would have to be increased to 2.7 million km. India's effort to involve the private sector in the provision of tolled roadways is outlined. Relevant provisions of the Seventh Five-Year Plan (1985-1990) and concerns of the private sector are discussed, and questions that remain to be resolved are summarized.

Pendse, D.P. (Tasa Industries, Bombay, India). *Transp Res Rec* 1107 1987 p 38-41.

**090640 ROADS—CAN WE NEGLECT THEM ANY FURTHER?** While only a subsidiary role was played by road transport in the past, it has now emerged as a major and essential infrastructure for growth and development of national economy. Road transport system has both flexibility and reliability, besides speed, door-to-door services, accessibility to remote areas and the highest employment generation potential as well. The article reviews three road development plans prepared for the country: the Nagpur Plan in 1943, the Bombay plan from 1961-81 and the 1981 to 2001 road plan.

Malhotra, J.M. (Indian Roads Congress, India). *Indian Highw* v 16 n 5 May 1988 p 5-8.

**090641 ROAD DEVELOPMENT IN THE STATE OF ASSAM: ACHIEVEMENTS AND FUTURE STRATEGIES.** The main achievements under the road development plans (Nagpur Plan and Bombay Plan) include the addition of roads; development of National Highways and removal of their deficiencies; building of road bridges and embankments. The task ahead calls for utmost sincerity and all out efforts from the engineering community. Technological innovations with the objective of making optimum use of locally available resources, tact and humility for obtaining complete co-operation and participation of the people, augmentation of fleet of plant and equipment to ensure maximum mechanised construction and judicious utilization of available financial resources are essential to achieve the objectives and targets laid down in the draft Master Plan of 1981-2001.

Gogoi, B.N. *Indian Highw* v 16 n 5 May 1988 p 15-21.

**Intersections** See Also HIGHWAY SIGNS, SIGNALS AND MARKINGS; STREET TRAFFIC CONTROL; STREET TRAFFIC CONTROL—Computer Applications; STREET TRAFFIC CONTROL—Management; STREET TRAFFIC CONTROL—Pedestrian Safety; TRAFFIC SIGNS, SIGNALS AND MARKINGS; TRAFFIC SIGNS, SIGNALS AND MARKINGS—Standards.

**090642 LAPTOP COMPUTERS MEASURE INTERSECTION PERFORMANCE.** Intersection level of service is defined in the 1985 Highway Capacity Manual as a function of the average delay per stopped vehicle on each approach. One solution to the problem of measuring intersection performance would thus be a computer program that calculates average stopped delay per vehicle and that runs on a small, laptop computer that could be used in the field. Intersection Delay (ISDELAY) is a straightforward program, written in a universal subset of BASIC, designed to measure stopped delay. This program should run with little or no modification on any laptop, or for that matter, any desktop computer with a BASIC interpreter. 2 refs.

Henry, R. David. *ITE J* v 57 n 6 Jun 1987 p 39-42.

**090643 DEVELOPMENT OF PASSENGER CAR EQUIVALENCIES FOR LARGE TRUCKS AT SIGNALIZED INTERSECTIONS.** The research reported in this article attempted to quantitatively measure the difference in operating characteristics between passenger cars and trucks traveling straight through a level, signalized intersection. The data collected were used to develop PCE (passenger car equivalent) values for trucks based on truck type and position in queue. Increasing the capacity of the intersection can be realized through signal timing optimization and improving the progression between intersections. 10 refs.

Molina, Cesar J. Jr. *ITE J* v 57 n 11 Nov 1987 p 33-37.

**090644 CAPACITY FACTOR OR CYCLE TIME OPTIMIZATION FOR SIGNALIZED JUNCTIONS: A GRAPH THEORY APPROACH.** In this paper a method for setting traffic signals of individual signalized junctions is presented. Capacity factor maximization and cycle time minimization are considered as objective functions. The correspondence between cycle time and capacity factor is discussed. The influence of minimum green and maximum red constraints is analyzed. Once this correspondence is known, an efficient problem-oriented algorithm, based on a PERT-like technique, is proposed for the solution of the problem. (Author abstract) 25 refs.

Cantarella, G.E. (Univ di Napoli, Naples, Italy); Improta, G. *Transp Res Part B* v 22B n 1 Feb 1988 p 1-23.

**090645 DELAY MODELS FOR MIXED PLATOON AND SECONDARY FLOWS.** A mathematical model is described for estimating approach delays at pretimed, signalized, coordinated intersections. The delay models incorporate the size of and flow rate within the progression bandwidth. Platoon dispersion and secondary flows are considered via a simplified platoon-dispersion algorithm calibrated from the TRANSYT-7F model. The basic premise in this study is that traffic is assumed to arrive at the progressed approach in two average flow rates one within the progression bandwidth, and another outside of it. This modeling concept represents a middle ground between bandwidth models that assume a constant flow rate in the dispersed platoon and TRANSYT-like techniques where arrival flow rates vary in each time slice of the cycle length. The delay models are evaluated with Webster's delay formula for random arrivals and with simulated data in NETSIM; in both cases the results compare very favorably. (Edited author abstract) 17 refs.

Rouphail, Nagui M. (Univ of Illinois, Chicago, IL, USA). *J Transp Eng* v 114 n 2 Mar 1988 p 131-152.

**090646 RODEL - AN ALTERNATIVE APPROACH TO ROUNDABOUT DESIGN.** Roundabout design has been traditionally evaluated against geometric and safety standards and by comparing forecast traffic flows with

capacity estimates. Designs that fulfil these criteria are normally considered satisfactory. However, the recent development of better equations for estimating capacities, queues and delays, together with the increased availability of computers, now enables the design and evaluation of roundabout layouts to be made in a manner not previously possible. To take advantage of these developments 'RODEL', a computer program for aiding roundabout design, has been developed. The program is fully interactive with simultaneous display of input and output. This enables the design engineer to experiment rapidly with changes in geometry while viewing the immediately displayed changes in queues, delays and delay cost. 4 refs.

Crown, R.B. *Highw Transp* v 34 n 10 Oct 1987 p 12-19.

**090647 MODELING CONFLICTS AT INTERSECTIONS HIDDEN BY VERTICAL CURVES.** A model that estimates the relative hazard to passenger cars stopping to turn left at an intersection hidden by a vertical curve is described. Monte Carlo methods are used to estimate the relative frequency of such hazardous incidents are serious conflict situations in which an accident could not be avoided by braking alone. Left-turn gap acceptance and headway distributions in opposing traffic are used in the model to determine the random delay experienced by left-turning passenger cars. Other random variables addressed in the model are traffic speeds, headways of cars following the left-turning car, and the perception reaction time of following car drivers. The results indicate that the conflict rates increase rapidly with decreasing sight distance. (Edited author abstract) 15 refs.

**Maintenance** See Also HIGHWAY ADMINISTRATION—Financing; HIGHWAY SIGNS, SIGNALS AND MARKINGS—Defects; HIGHWAY SYSTEMS—Service Areas; MUNICIPAL ENGINEERING; PAVEMENTS—Asphalt; PAVEMENTS—Concrete; PAVEMENTS—Evaluation.

**090648 HOW DOTS IMPROVE EQUIPMENT MANAGEMENT AND MAINTENANCE.** The top equipment management and maintenance problems are people problems, according to results of a recent Better Roads' survey. Nearly half - 48.3% - of the equipment managers responding cited the difficulties in finding and keeping competent workers, dealing with top departmental management, and training personnel as their most critical problems. The need for more or better operator training was cited as the most important equipment maintenance problem. Equipment management systems are the solution to some of the problems, according to many maintenance engineers who are using them. Additional survey results are discussed.

Anon. *Better Roads* v 57 n 10 Oct 1987 p 22-31.

**090649 SOFT WEAR FOR ROADS.** Since documented justification for allocating scarce financial resources usually is demanded, a comprehensive pavement-management system can help ensure wise budget expenditure and increase the life of existing roads. According to the American Public Works Association (APWA), local agencies are adopting pavement-maintenance management systems for a variety of reasons: to inventory existing facilities, such as pavement structure, light poles and inlets; justify maintenance budget increases; prioritize maintenance needs; and provide better roads for less money. APWA initiated a research project called PAYER through its Research Foundation in 1979. The program was developed by the U.S. Army Corps of Engineers at its Construction Engineering Research Laboratory, Campaign, Ill., for pavement management at military bases.

Buchholz, John D. *Am City Cty* v 102 n 9 Sep 1987 p 76-78, 80, 84-85.

**090650 CLOSER LOOK AT IMPACT FEES.** Localities in five states use impact fees (charges collected during approval of land development) to support public facilities

to serve proposed development. Such fees are especially useful for funding improvements in suburban and fringe areas where development pressures are particularly strong and land is readily available. In this paper the emphasis is on impact fees for roadway improvements; some of the topics addressed are developers' concerns, determining traffic impacts, attracting development, and planning considerations. (Author abstract) 11 refs.

Draper, Robert W. (US DOT, Washington, DC, USA). *Transp Res Rec* 1107 1987 p 68-73.

**090651 IMPACT FEE ASSESSMENT USING HIGHWAY COST ALLOCATION METHODS.** Impact fees have been assessed as flat fees based on the size of the development; variable fees depending on the type and location of the development; and negotiated fees determined by the required investments, the interests of the local communities, and the resources of the developer. Variable fees are analogous to roadway user taxes in that roadway costs vary with traffic and a desired revenue target is to be met. Techniques used in highway cost allocation studies can be directly applied to the design of equitable variable impact fees. Because highway cost allocation studies have received considerable attention and have been widely applied, these allocation methods might be usefully adopted for impact fee assessment. (Edited author abstract) 24 refs.

**090652 ZUSAMMENHÄNGE ZWISCHEN DEM STRASSENZUSTAND UND DEM UNFALLGESCHEHEN, DEM ENERGIEBEDARF SOWIE DEM ZEITAUFWAND.** [Relation Between Road Conditions and Accidents, Energy Demand and Time Required]. Evaluation of suitable methods for road maintenance and an economic use of limited finances require reliable knowledge about the relations between road conditions and accidents, transportation energy demand and the time spent by traffic participants for travel. Based on an evaluation of literature, a survey of this subject is presented. Causes of accidents are analyzed and related to insufficient road roughness and slippery conditions. The energy demand depends on the routing. Unpaved roads have a high energy demand. Rolling resistance influences the energy consumption. Unevennesses require more fuel and time. Speed measurements of different road surfaces show that the difference between mean speeds lies within the range from 1 to 5 km/h. Further research is still required. (Translated author abstract) In German. 15 refs.

**090653 ROAD REHABILITATION IN NOVA SCOTIA.** Various rehabilitation methods have been experimented with in Nova Scotia over the years to adapt maintenance processes to climatic conditions. Three specific maintenance methods will be discussed: sand sealing, crack sealing, and seal coating. For each method, material acceptance, placement, and evaluation of the end result will be examined. Special emphasis will be placed on Nova Scotia's experience and modifications that have made an efficient rehabilitation program. (Author abstract) 2 refs.

**090654 CITY PUTS THE BRAKES ON PAVEMENT AGING.** The article discusses a technique employed for some 20 years in Abilene, Texas to overcome the problem of new pavement deterioration. The technique relies on an asphalt rejuvenating agent, Reclamite preservative seal, manufactured by Witco Corporation's Golden Bear Division, Los Angeles. Cores showed that the agent has a compatibility with asphalt that makes it virtually a 'partner' in delaying deterioration. Today the city is getting six to eight years before any surface maintenance is required. Pavements were tested in the

field to determine the amount of material that would penetrate in one hour. Subjects covered include test methods and the application process.

White, C. L. Jr. *Public Works* v 118 n 12 Dec 1987 p 44-45.

**090655 MAINTENANCE OF ROADS IN HIGH ALTITUDE AREAS.** Motor roads and bridle roads at high altitudes less than 3000 meters in sub-Himalayan terrain are used to serve the scattered population, but their special utility is in guarding the borders at higher altitudes. These bridle roads at higher altitudes are termed border tracks. Maintenance of such bridle roads and tracks is very difficult. There are special problems associated with it, which the paper discusses, based on the author's experience of working for about 6 years in such areas and the problems that have been experienced.

**090657 KONZEPT FÜR DIE ZUSTANDSERFASSUNG UND -BEWERTUNG IM INNERORTSBEREICH.** [Concept for the Recording and Evaluation of Pavement Conditions in Inner City Areas]. Within the framework of road maintenance management, a considerable importance is allotted to the recording and evaluation of the road surface conditions by means of the proposed systematic recording of partial aspects (damages, defects) and their evaluation, not only an objective priority ranking of the necessary works is made possible but also recommendations can be made regarding the expedient maintenance measures. An outline of the procedure is presented and some details, evaluation possibilities and costs are explained. (Translated author abstract) 3 refs. In German.

Maerschalk, Guenther (Univ Bundeswehr Muenchen, Neubiberg, West Ger). *Bitumen* v 49 n 1 First Quarter 1987 p 13-18.

**090658 ROADWAY REBUILT WITHOUT OFFENDING MOTHER NATURE.** A unique solution was required to rehabilitate Grand Tour - a narrow, 80-year old rural New Jersey roadway located on the edge of a 20-ft high bluff overlooking a large pond. Soil borings and an analysis of slope conditions confirmed a stability failure and provided the basis for a series of recommended solutions for stabilization. The unique solution featured lowering the top of the bluff about six feet to create an acceptable rate of grade down the slope. The solution, stepping the grade, was accomplished by lowering the roadway approximately three feet, using a 3-ft high brick face reinforced concrete wall along the in-land side of the road. In addition, a 3-ft high gabion retaining wall was constructed on the cliff side of the road. This design enabled the improvements to be built immediately and adjacent to the existing road.

**090659 BESEITIGUNG VON WINTERSCHADEN.** [Repair of Damaged Concrete Pavement as a Result of Wintry Weather Effects]. The causes of concrete pavement damage due to severe winter conditions are considered. Some answers are given generally and in some cases exemplified by pictures. The most frequently used repair material is a mixture of epoxy resin and dry quartz sand. It is to be applied with a deep sealing solution. Its application is described. (Edited author abstract) In German.

Grunau, Edvard B. *Str Tiefbau* v 42 n 5 May 1988 p 21-26.

**090660 LOCAL TRAFFIC ENGINEERING: WHERE ARE WE?** Most local governments in the United States manage and maintain streets and roads as part of their everyday duties. How well are local governments handling their responsibilities with respect to nationally accepted traffic engineering procedures and standards? To find out how local agencies in Tennessee were doing, a survey of every city and county in the state was conducted during the fall of 1987. Local governments that maintain roads need to understand the importance of following nationally accepted standards. It is clear from this survey that not all governments are following these standards. This paper analyzes the basic objectives of the survey: decision making on traffic control; signing and striping responsibilities; accident recording systems; usage of traffic control devices. 9 refs.

**090661 GOOD REASONS TO USE HERBICIDES IN THE FALL.** Fall spraying is less likely to result in complaints from the public. About 53 percent of vegetation management supervisors recently surveyed by Better Roads' editors report receiving fewer complaints about fall herbicide use. Study results are discussed in terms of herbicide use frequency, reasons for fall spraying, dealing with public reactions, types of herbicides used in the fall, and other related subjects.

Anon. *Better Roads* v 58 n 8 Aug 1988 p 44-45.

## Management

**090662 RESIDENTIAL STREET MANAGEMENT IN SOUTH AUSTRALIA.** From the early 1900s to the late 1940s, road networks in South Australia were developed on the rectangular grid system as an extension to the original planning of early towns and villages. In the late 1940s to the late 1970s curvilinear road systems with offset intersections and an imposed hierarchy became the norm for development in residential subdivisions. Major road standards were applied to the planning, design, and construction of all streets and roads, and allowances were built in the pavement widths and depths to provide for continuing traffic growth. Current practice generally tends to follow the preceding principles with some modifications to achieve more cost-effective designs and to minimize some of the operating problems evident with such systems. 13 refs.

**090663 MONTE CARLO TECHNIQUE TO DETERMINE THE EFFECTIVENESS OF ROADSIDE TREES FOR CONTAINING TRAFFIC NOISE.** A computer-generated simulation of noise attenuation by foliage of trees lining urban roads has been carried out. For the simulation of foliage the program uses experimentally measured leaf parameters as input variables. A geometrical reflection model is assumed for the noise

trapped by the tall building facades parallel to the road. The results show that belts of trees do not significantly attenuate traffic noise at ground level but, for elevated levels, effective attenuation of the traffic noise occurs, especially at the higher-frequency end. (Author abstract) 9 refs.

**090665 AKTIVER LAERMSCHUTZ MIT BETON.** [Active Noise Insulation with the Aid of Concrete]. It is a commonly known fact that in the long run noise causes damage to people's health. Therefore it is necessary to reduce the nuisance to a minimum for the people living close to noisy roads. In case it is not possible to reach that aim by structural or planning measures next to the streets there are earth walls and noise insulation walls to protect people from traffic noise. The requirements and design principles of concrete noise insulation walls are the subject of this contribution. (Edited author abstract). In German.

Kommer, Eleonore. *Beton* v 38 n 5 May 1988 p 178-181.

**Noise, Acoustic** See Also AUTOMOBILES—Noise.

**090666 TRAFFIC NOISE SPECTRA IN DRY AND WET STREET CONDITIONS.** The traffic noise surveys reported in the literature traditionally have been done in dry weather conditions. Studies concerning the influence of weather factors, such as rain, on the overall level produced by vehicles have been restricted to studies on the tire noise of single vehicles where increases as high as 10 db(A) have been observed. Few studies have undertaken the measurement of traffic noise spectra of levels produced by urban traffic in rainy conditions. During the course of some studies on urban noise undertaken in certain areas of Mexico City, there was an opportunity to make some recordings on rainy days and some on dry days, and to compare the spectra recorded under these conditions. Some measurements of noise levels were made and compared under these conditions but, due to the variability of traffic flows, it was difficult to make enough recordings in which the conditions were similar, or to take a statistical sample representative enough to make the comparisons. This note primarily refers to the spectra, but some comments on findings with respect to noise levels are made. (Edited author abstract) 4 refs.

**090667 OPTIMAL STRATEGY ON TRAFFIC CONTROL TO REGULATE STREET NOISE OVER A WIDE CITY AREA FROM TWO METHODOLOGICAL VIEWPOINTS OF DYNAMIC PROGRAMMING AND MAXIMUM PRINCIPLE.** The resultant fluctuation patterns of environmental road traffic noise can be principally described by many factors concerning traffic flow and sound propagation. From this point of view, in this paper a new criterion index to evaluate the street noise over a wide city area is initially introduced in a functional form related to the  $L_{eq}$  evaluation, in close connection with physical parameters of traffic flow and sound propagation characteristics. Then, the optimal control strategies on traffic flow to regulate the street noise over a wide area are generally determined from two methodological viewpoints by use of dynamic programming and maximum principle. Finally, the validity and effectiveness of the proposed method are confirmed, especially by means of digital simulation. (Author ab-

stract) 3 refs.

## Norway

**090671 THE TOLL RING IN BERGEN, NORWAY.** On January 2, 1986, the city of Bergen implemented a toll ring around the central business district (CBD). The Bergen toll ring and the Area License Scheme in Singapore are the only examples known to this author of vehicles being charged a toll for entering the CBD. This paper is about the recently opened toll ring around Bergen, Norway. The physical characteristics of the toll ring - toll stations, methods of payment, reserved lanes, and control system - are described. The toll ring is successful because it was introduced to raise funds for badly needed major improvements to the road system not to restrain traffic. 2 refs.

Larsen, Odd I. (Inst of Transport Economics, Oslo, Norw). *Transp Res Rec* 1107 1987 p 41-45.

## Performance

**090672 URBAN ROADS - SOME CURRENT AND FUTURE ISSUES.** This paper summarizes past and likely future trends in population, motor vehicle ownership and urban road travel. It refers to a comprehensive study of urban arterial roads, of their traffic performance in 1981, and of projections of their traffic performance in 1991. It then discusses some current issues relating to, and expenditure on urban roads. Finally, the paper comments on the future outlook for urban roads. It concludes that finance will continue to be of major concern in the future, and suggests some alternative means of financing urban arterial road works. (Author abstract) 23 refs.

## Reliability

**090676 BEWERTUNG DER BEANSPRUCHUNGSSTREUUNG AUS GEMESSENEN KOLLEKTIVEN.** [Valuation of the Intensity of Measured Load Spectra]. Measured load spectra, for example on a specific road

driven by several drivers, show different distributions. The question is how to determine the scatter of loading if the spectra differ in size and frequency of load cycles. The investigation shows that the scatter of loading can be expressed as the scatter of the calculated damage sum. In this way, for a reliability analysis, the mean value and the (logarithmic) standard deviation can be taken into account. (Author abstract) In German. 8 refs.

Guethé, Heinz-Peter; Petersen, Juergen; Vogler, Josef; Zenner, Harald. *Automobiltech Z* v 89 n 12 Dec 1987 p 679-680, 684.

**090677 EFFICIENT CALCULATION METHOD TO OBTAIN UPPER AND LOWER BOUNDS OF TERMINAL RELIABILITY OF ROAD NETWORKS USING BOOLEAN ALGEBRA.** This paper proposes a new method to estimate upper and lower bounds of reliability between node pairs in road networks. The conventional calculation methods using all the minimal path sets and cut sets are impractical for a large system since the path sets and cut sets include a large number of elements. The proposed method is quite useful since it requires only partial minimal path sets and cut sets. An efficient way of selection of the paths and cuts is investigated, and an algorithm for a Boolean manipulation is developed. Also a numerical example of small size network is executed to examine the validity of the method. (Author abstract). 16 Refs. In Japanese.

## Repair See Also PAVEMENTS—Maintenance; PAVEMENTS—Repair.

**090678 DEMONSTRATION SHOWS VALUE OF ASPHALT REHABILITATION.** In Ohio, Richland County and the city of Mansfield were recently on the receiving end of a demonstration project, aimed at providing the value of rehabilitating and asphalt road. The contractor, Kokosing Construction, used a Bomag MPH-100 recycler for the work. There were three test areas completed on Cairns Road. The first is a full-width section 1,000-ft. long by an average of 25-ft. wide. The second and third test areas were on an 800-ft. long section of road with an average width of 22 ft. Use of the Bomag machine and method to rehabilitate a road saved 47% over other rehab methods.

**090679 DUENNE SCHICHTEN IM KALTEINBAU.** [Cold-laid Thin Courses]. The general aim of road rehabilitation and maintenance is to restore a long-lasting good in-service performance at low costs. The German Road and Traffic Research Society (FGSV) is studying the relevant methods for elaboration of recommendations and rules to guide the road authorities. Its studies comprise among others the technique of cold laying of thin rubber-modified asphalt courses, excelling in high wear resistance and durability. Subjects of the paper are composition of such cold mixes, equipment for mixing and applying them, and further particular features of the technology. (Edited author abstract) In German. 3 refs.

Neis, Heinz (Raschig AG, Ludwigshafen/Rhein, West Ger). *Str Tiefbau* v 42 n 1 Jan 1988 p 21-22.

**090680 RESTORING UTILITY CUTS IN CONCRETE STREETS.** Concrete streets are especially forgiving of utility cuts. A new concrete section is either aggregate interlock or dowel bars. The replacement concrete can be struck off even with the surrounding pavement, leaving no lip or depression. Concrete's structural strength means that the repair section can bridge at least some future settlement of the backfill. A long-lasting utility cut repair involves more than 'shovelling in a little hot mix'. Considerations include the size and shape of the cut, proper removal of the concrete, backfilling materials and compaction, and concrete replacement. Each of these points is discussed in the article.

**090681 DYNAMIC ANALYSIS OF LANE CLOSURE STRATEGIES.** A dynamic simulation model is extended to represent traffic system disruptions in the form of lane closures. The model has two components: a macroparticle traffic simulator, and a user decision component which comprises behavioral mechanisms governing the daily departure time decisions of commuters. The model is applied to the analysis of six alternative lane closure strategies associated with planned repair activities. Examples of model results are described, highlighting the tradeoffs between the performance of the system during the perturbation period and the final equilibrium state, as well as the trade-off between the schedule delay and the travel time experienced by system users during those periods. **090682 OPTIMIZATION: THE KEY TO ROADWAY IMPROVEMENTS.** Commercial and residential development in many parts of the US has caused a significant increase in traffic volume on existing roads. By resurfacing, restoring, rehabilitating, and reconstructing existing roads, transportation authorities can increase capacity and traffic safety and improve operating conditions without causing major public or environmental impacts. Because there is less community and regulatory resistance to roadway improvements than to new construction, they can be carried out in a relatively short time frame. They can also be implemented in stages, if necessary, to accommodate budget restrictions.

Urban, John (Edwards & Kelcey, Livingston, NJ, USA). *Public Works* v 119 n 8 Jul 1988 p 59-60.

## Roughness Measurement

**090683 EXTERNAL METHODS FOR EVALUATING SHOCK ABSORBERS FOR ROAD ROUGHNESS MEASUREMENTS.** Two new experimental methods are described for the selection of shock absorbers for response-type road roughness meters. The methods allow for verification of the acceptability of the shock absorbers before they are mounted in the road roughness measuring vehicle. In the first method, a programmable shaker table is used to obtain the time response of the shock absorber. In the second method, a simple scotch yoke mechanism is used to produce the frequency response of the shock absorber. In both methods, the test results are compared with the corresponding time domain or frequency domain acceptability limits, which are determined from computer simulation and based on the relevant ASTM standards. (Author abstract) 5 refs.

**090686 ROAD MAINTENANCE: MODIFIED RECYCLER MASTERS FOAMED BITUMEN IN LOCAL ROADS RENEWAL.** The recent re-emergence in the UK of structural mix-in-place recycling for the maintenance of failed or failing residential and unclassified rural roads gained a new dimension with the commissioning of the first UK plant purpose-built to perform foamed bitumen stabilization. The process, which expands hot pen grade bitumen from ten to fifteen times its original volume, will provide highway engineers with an alternative to cement and bitumen emulsion when they consider stabilization for the structural rehabilitation of their roads. The main advantages of mix-in-place recycling using foamed bitumen, as with cement and bitumen emulsion, are cost-savings and speed.

Anon. *Highways (Croydon Engl)* v 55 n 1927 Jul 1987 p 11, 24.

**090687 FINANCING, PRIVATE-SECTOR INVOLVEMENT, AND MARKET PROCESSES IN THE PROVISION OF NATIONAL ROADS IN SOUTH AFRICA.** This paper describes the changing basis of the provision of rural roads in South Africa that led to the introduction of toll roads and, in the process, to an increasing degree of privatization in the provision of roads. The background financial and administrative arrangements for the provision of rural roads is discussed and national policy that influences the financing of roads are described. With the increasing shortage of funds for roads during the past decade, the need for better economic justification of specific road projects and the search for new sources of funds combined with the policy of user charging and of supporting the free market system has had a significant effect on the development of the rural road system. (Edited author abstract) 1 ref.

**090688 PLANNING AND DEVELOPMENT OF RURAL ROAD NETWORKS IN DEVELOPING COUNTRIES.** Rural road planning in developing countries is defined and differentiated from other types of road investments. Various approaches to the problem are assessed; a new network modelling approach is proposed and a combinatorial tree design problem is formulated as the basic decision model; solution techniques of mathematical programming, exact enumerative and heuristic methods are presented. Experience with test problems indicates that the proposed heuristic performs satisfactorily. Attention is given to the use of solutions in the context of real world decisions. In the framework of developing countries, the new approach seems to be more practicable than any conventional method. (Author ab-

stract) 27 refs.

Van Oudheusden, Dirk L. (Asian Inst of Technology, Bangkok, Thai); Khan, Lutfar Rahman. *Eur J Oper Res* v 32 n 3 Dec 1987 p 353-362.

**090689 OPTIMIZING RURAL ROAD CONSERVATION EXPENDITURES.** A methodology of optimizing expenditures for rural road maintenance and rehabilitation is presented. The optimum schedule for pavement overlay and rehabilitation is determined resulting in minimal costs during the road's economic horizon. In developing countries, the economic horizon usually varies between 10 and 20 years; in Ecuador, it was established at 17 years. During this period most of the road's socioeconomic benefits are obtained. The economic residual value is small relative to other transportation expenditures. Total expenditures during the service lifetime include construction, maintenance, pavement overlay or rehabilitation, and vehicle-operating costs. An optimal programming methodology is presented for pavement overlay as a function of road type, traffic volume, type of terrain, and maintenance level. (Edited author abstract) 14 refs.

**090690 MAINTENANCE OF ROADS IN HIGH ALTITUDE AREAS.** Motor roads and bridle roads at high altitudes less than 3000 meter (10,000 ft) in sub-Himalayan terrain may be used to serve the scattered population but their special utility is in guarding the borders at higher altitudes. These bridle roads at higher altitudes are termed as border tracks. Maintenance of such bridle roads and tracks is very difficult and there are special problems associated with it. These special problems cannot be guessed unless someone works at higher altitude. In this article, experience of working for about 6 years in such areas and the problems that have been experienced are highlighted.

Bhakuni, H.S. (PWD, Askote, India). *Indian Highw* v 16 n 1 Jan 1988 p 5-7.

## Scotland

**090691 KILLIECRANKIE PASS, SCOTLAND.** An area of great scenic beauty, the narrow steep-sided valley of the Killiecrankie Pass in Scotland is invested with concrete viaducts and retaining walls of excellent workmanship. Simple but pleasing in appearance, the new A9 trunk road hugs the hillside while the structures are endowed with unity of concept, fineness of purpose, economy, ease of maintenance and durability - prime factors in their design and construction. Despite their grand scale the structures have blended admirably with the surrounding countryside, with the minimum of disruption to a region of historical and scenic importance. This article discusses the design concept of the road, and design and construction of the retaining walls and viaducts.

**Service Life** See PAVEMENTS—Bituminous.

**Shoulders** See HIGHWAY ENGINEERING.

**Skid Resistance** See Also PAVEMENTS—Brick Construction; PAVEMENTS—Concrete; TIRES—Performance.

**090692 SKID RESISTANT BY DESIGN.** This paper introduces the principal factors affecting microtexture and macrotexture which create the skid resistance of a road pavement. These are related to the special factors of the non-homogeneous surface of a concrete block pavement. The performance of concrete block pavements in service is described and related to the minimum requirements for skid resistance measured by the SCRIM machine and pendulum test. In the case of concrete block pavers, the microtexture will be affected by the method of manufacture, i.e. the extent to which the upper surface of the paver contains a mixture of coarse and fine aggregate, or merely a mortar paste. In this case a test called Polished Paver

Value (BSI/DD 155)<sup>2</sup> has been developed to simulate in-service polishing. 12 refs.

**Snow and Ice Control** See Also BRIDGES, CONCRETE—Repair; HIGHWAY SYSTEMS—Maintenance; PAVEMENTS—Concrete; SNOW PLOWS; WATER POLLUTION.

**090693 PREWETTING AIDS CANADIAN SNOW CONTROL.** Prewetting sand and salt with calcium chloride is helping two Alberta cities deal with winter. Even in -20-degree C weather, the treated mixture of sand and sodium chloride did its job in storms experienced by Calgary. In Lethbridge, a city by-law restricts the use of salt to the hills and underpasses of major roads. Other roads use sand alone or a mix of 95% sand and 5% salt. On urban roads, pre-wetting with calcium chloride has cut the amount of sand required by 40%. Even without salt, some melting action takes place down to around -5 degrees C.

Anon. *Better Roads* v 57 n 11 Nov 1987 p 34, 36.

**090694 CORROSIVITY TESTS PIT ROAD SALT vs. CMA.** The article reports on an experimental study to compare the corrosive effect of a 1.0 percent aqueous solution with a 0.60 percent aqueous road salt solution, and with water on a type of steel reinforcing bar commonly used in Milwaukee. Three rebars each were tested in aerated and unaerated CMA, road salt, and water. In all, 18 rebars were used. The CMA used in this experiment was manufactured by Gancy Chemical Corporation, Syracuse, New York and furnished by the Federal Highway Administration, McLean, Virginia. The road salt tested is the type used by Milwaukee for deicing streets. Study materials, methods and results are discussed. Refs.

**090697 SALT - A GUIDE TO REGULATING ITS USE.** Calcium magnesium acetate (CMA) is the leading candidate for replacement, but only rock salt reduces the amount of salt's corrosion and is quite expensive with costs ranging from \$450 to \$500/t. compared to \$24 to \$40/t. for salt. The more important functional properties of rock salt in a winter maintenance operation are: the ability to form a brine that coats the snow particles to prevent packing and bonding of snow to the pavement; the ability of salt particles to dissolve slowly from their solid state; the ability of salt to melt snow and ice easily with temperatures of 20 degrees F and above; salt's low hygroscopic property; easy storage and treatment to resist caking. This article discusses techniques employed by the Michigan Department of Transportation to use salt effectively, efficiently and economically.

O'Toole, Martin L. (Michigan DOT, USA). *Better Roads* v 58 n 2 Feb 1988 p 41-42.

**090698 EFFECT OF ROADWAY SALTING ON SAFETY AND MOBILITY.** The research detailed in this report represents a preliminary effort to develop an understanding of the effects of roadway salting on road safety and mobility. Analyses included an assessment of available literature, the review of accident data from a number of sources, and the development of a study procedure for assessing the effects of winter conditions and maintenance activities on vehicle operations. The procedure developed was based on vehicle headway observations. Field trails of the study procedure in six different jurisdictions confirmed it to be sensitive to roadway conditions, and to be capable of reflecting the effects of maintenance activities. Results of the studies showed little variation for mean headways under dry, wet, and slushy road conditions. Mean headways under snow or icy road conditions were much larger. Limited study of the effects of maintenance activities suggested that different roadway salting strategies had little differential effect on vehicle headways. Finally a variety of study refinements were identified. Additional aspects of the study are discussed. (Edited author abstract) 3 refs.

**090699 EINFLUSS DES TAUSALZES AUF OBERFLAECHE- UND GRUNDWASSER.** [Effect of Thawing Salt on Surface and Ground Water]. Between 1965-1974 the annual consumption of salt on the roads of the Federal Republic of Germany amounted to 892,900 t, i.e. 1996 t/km. In Great Britain it was 2.97 t, in the Netherlands 5.76 t, in Belgium 0.36 t/km. In the 1979-1984 period, the greatest use of salt was in 1979, namely 3.0 Mt, in the year 1983 the lowest, namely 878,000 t. The dissolved salts are distributed below surface and in groundwater depending on the type of soil. The result of measurements carried out in the area of Augsburg, Munich and Kaufbeuren in 1976-1979 are reported. Some measures to minimize the effect of the salt on groundwater are recommended. (Edited author abstract) In German. 2 refs.

Bischofsberger, Wolfgang (TU Muenchen, Garching, West Ger). *Str Autobahn* v 38 n 5 May 1987 p 192-197.

**090700 COMPARING CHEMICAL DEICERS.** Ice penetration and melting characteristics of deicers were studied recently. It was found that calcium chloride initially penetrates ice - at all temperatures - at a rate about twice that of other deicers. Sodium chloride penetrates initially at a lower rate than calcium chloride; it performs similarly to calcium chloride over a 45- to 60-minute period at 15 to 25 degrees F. Urea and potassium chloride are substantially less active than sodium and calcium chloride. From the standpoint of undercutting and ice disbondment, the order of preference is  $\text{CaCl}_2$ ,  $\text{NaCl}$ ,  $\text{KCl}$ , and urea. Sharp-edged crystal deicers, such as sodium chloride, tend to behave differently than spherical deicers. Calcium chloride is superior from the standpoint of ice-melting volumes and ice penetration/undercutting in the early stages of ice melting. Deicer blends tested were equal to or less effective than sodium chloride - at all test

temperatures. Additional study results are discussed.

Anon. *Better Roads* v 58 n 6 Jun 1988 p 28, 30.

**090701 CMA AND SALT MIX CUTS CORROSION.** Studies by the Michigan Department of Transportation of the corrosion performance of calcium magnesium acetate (CMA) and CMA-rock salt mixes suggests that the more economical mix may provide almost as much corrosion protection as CMA by itself. Since it appears that more rock salt than CMA can be used in such a mix, it is likely that the mix will also retain many of the beneficial deicing advantages of salt - such as a lower melting temperature. CMA and salt mixtures retain much of the corrosion protection provided by CMA alone. Current data indicate one part CMA to two parts salt result in a mixture that provides corrosion protection that almost equals CMA alone. The mixture would cost less than seven times the cost of salt by itself at current prices. These and other aspects of the subject are discussed.

## Testing See Also VEHICLES—Testing.

**090709 PEAK SIDE FRICTION AND YAW RATE DURING SURVEY OF HUME HIGHWAY.** The ARRB Road Geometry Survey Vehicle was used to survey the Hume Highway, from Melbourne to Sydney and return, during the week beginning April 28, 1986. As the actual vehicle travel speed is included, it is possible to calculate back to the side friction demand and the yaw rate of the vehicle at any point during the survey trip. This has been done, and the peak values throughout the trip for each speed value have been determined. The calculations and their results are discussed. 6 refs.

Rawlinson, W.R. (Australian Road Research Board). *Aust Road Res* v 17 n 2 Jun 1987 p 129-131.

**090710 DEFORMATION OF ROAD FOUNDATIONS WITH GEOGRID REINFORCEMENT.** The deformation under traffic of crushed rock sub-bases over clay subgrades has been investigated; the experiments included an investigation of the effectiveness of a reinforcing geogrid between the sub-base and the subgrade. Sections with and without reinforcement were trafficked simultaneously by a rigid two-axle lorry with its rear axle

loaded to about 80 kN and the number of vehicle passes to cause 40 mm deformation at the sub-base surface was related to the sub-base thickness, subgrade strength and the use of geogrid. Transverse trenching revealed the accumulated deformation in the sub-base and subgrade. The results were compared with existing designs for foundation layers and the performance of the reinforcement was examined over a wide range of test conditions. (Author abstract). 10 Refs.

Chaddock, B.C.J. (Transport & Road Research Lab, Crowthorne, Engl). *Res Rep Transp Road Res Lab* n 140 1988 p 1-8.

**090711 TESTING VEHICLE HELPS EVALUATE ROAD PAVEMENTS.** A road testing vehicle was developed in Australia which measures the strength and stiffness of a pavement while traveling along the road. The vehicle is constructed on a MAN bus chassis, configured to produce a load of 8.2t on its dual-tired single rear axle. The passage of the loaded vehicle produces a deflection in the pavement and both the maximum deflection and the shape of the deflection bowl are measured. The maximum deflection relates to the pavement strength and is the parameter for pavement rutting, while the deflection bowl shape relates to the pavement stiffness and is the parameter for fine fatigue cracking in the asphalt. The vehicle is able to measure deflections at speeds from 2km/h to 8km/h with distances between measurements being in the range of 4m to 11m. The high measurement speed allows up to 50 lane-km of pavement to be tested per day.

## Vibrations

**090712 ON THE FORCE APPLIED TO THE ROAD BY AN AUTOMOBILE RUNNING OVER A BAR-LIKE PROJECTION ON THE ROAD.** An experimental expression of the restoring force of a tire compressed by a flat plate and a dull edge is derived. Using this expression, equations of motion of a light truck that runs over a low bar-like projection placed normal to the direction of the motion of the truck are set up. These equations are solved by a numerical method in the situation that the left-hand wheels of the truck run over the projection. Based on the solution, the force applied to the road by the truck in this situation is calculated. Experiments are made to measure the force applied. A force-measuring device equipped with a force-receiving flat top plate is settled in the road with the top plate flush with the road surface, and a bar-like projection is attached to the top plate. The force is measured when the left-hand wheels of the truck run over the device. It is concluded that the results of calculation show good agreement with those of experiment. (Author abstract) In Japanese. 8 refs.

## Japan

**090715 PRESENT STATUS OF JAPAN'S ADVANCED ROBOT PROJECT.** For realizing advanced robots, numerous state-of-the-art technologies including electronics, communications, measurement, control, mechanics and material science have to be developed and combined. Advanced robotics R&D in Japan has been selected as a national project 'Advanced Robot Technology' under the National Research and Development Program. The project has been directed towards establishing the technologies for advanced robots to carry out inspection, maintenance, rescue operations and other complex tasks under dangerous environments that do not allow direct human labor. Specifically, R&D activity in the project has concentrated on robots which meet the needs in the fields of nuclear power plants, undersea and fire fighting (i.e., nuclear power plant robot, undersea robot and fire fighting robot). R&D activities have been assigned for the general technologies required for these three fields of advanced robots.

Okada, Yasushi (MITI, Tokyo, Jpn). *Ind Robot* v 15 n 1 Mar 1988 p 35-38.

**Remote Control** See SPACECRAFT—Robot Applications.

**ROBOTIC ASSEMBLY** See Also ASSEMBLY MACHINES—Automation; AUTOMOBILE ENGINE MANUFACTURE—Robot Applications; PLASTICS PRODUCTS—Assembly; PRINTED CIRCUITS—Assembly; ROBOTICS—Planning; ROBOTS, INDUSTRIAL—Electric Drive; ROBOTS, INDUSTRIAL—Sensors.

**090716 ADEPT AIDS ADEC'S PRECISION IN INDUSTRY.** Adec is a Swiss distributor of the AdeptOne direct-drive robot, which is central to the turnkey systems and applications engineering divisions. The key division is turnkey systems, which are concentrated into four areas: mechanical part assembly, clean-room applications, PCB assembly and packaging systems. All systems are robotic-based and now only Adept robots are used - in the early days of the company it did install one or two systems with Unimation PUMA robots. Using only Adept products is not a rigid policy and other types could be incorporated if necessary.

Rooks, Brian. *Assem Autom* v 7 n 3 Aug 1987 p 127-129.

**090717 CURRENT HARDWARE CONFIGURATIONS IN ASSEMBLY AUTOMATION.** The author emphasizes the importance of considering sub-system components of assembly automation systems; feeder and presentation systems. Apart from the as-designed features, the engineer should also anticipate foreseeable changes in the system environment, and plan for them. The use of case studies very well illustrate these points. These included the design of an automatic system to assemble electric-socket elements and three-pin plugs.

McClelland, Stephen. *Assem Autom* v 7 n 3 Aug 1987 p 145-146.

**090718 ASSEMBLY SYSTEM OF A HEAVY WORKS SUSPENDED BY A WIRE USING A SMALL-SIZE ROBOT.** This research deals with a

control system to handle heavy works with a small-size robot. The heavy work is suspended by a wire and the robot inserts it into a square shaped hole. To avoid an impulse force resulting from the collision of the work and the hole, a parallel spring beam is installed at the tip of the end-effector. Since the spring causes vibration of the work during positioning, a bang-bang control is introduced to decrease its amplitude. The residual amplitude is 2 mm, much smaller than its original 30 mm. (Edited author abstract) In Japanese. 2 refs.

Arai, Tamio (Univ of Tokyo, Jpn); Osumi, Hisashi. *J Fac Eng Univ Tokyo Ser A* n 24 1986 p 18-19.

**090719 ROBOTS AND MECHANICAL ASSEMBLY.** Robot industry participants and observers have long predicted the rapid growth of robots for use in assembly tasks. In the past two years, their predictions have begun to materialize as the use of robots for assembly has grown from a \$35 million market in the US in 1983 to a projected \$100 million in 1985. Mechanical product assembly represents a significant portion of the assembly tasks being performed by assembly robots today. The automotive and disk drive industries have moved decisively to employ robots for assembly of product components and final products. The paper describes how a new generation of fast, integrated robot systems will speed the penetration of robots in mechanical assembly applications.

Wood, Elaine Ide. *Rob Today* v 7 n 3 Jun 1985 p 53-55.

**090720 LOCKHEED ELECTRONICS CENTER LINKS DESIGN AND PRODUCTION: AUTOMATED FACILITY PRODUCES PRINTED CIRCUIT BOARD ASSEMBLIES.** Lockheed's \$40 million Automated Center for Electronics in Sunnyvale, Calif., links all phases of electronic circuit design, development, assembly and test to produce high-quality printed circuit board assemblies for ground and flight applications. The 213, 000-square-foot Lockheed Missiles & Space Co. center unites 200 computer-aided work stations for design and engineering with an assembly line of robotic and automated insertion equipment, and test and process controls. The center combined electronic circuit design development with automated assembly, testing and process control.

Anon. *Rob World* v 5 n 12 Nov 1987 p 26-27.

**090721 ROBOT ASSEMBLY OF PRECISION PARTS USING TACTILE SENSORS.** If the positioning control type robot is to be used for part fitting work, it is necessary to describe the loci of the parts accurately with respect to the robot's coordinates and to control the business end of the robot according to those loci. Mechanical error in the robot itself and control error cannot be eliminated completely. However, it is extremely difficult to improve absolute positional accuracy. Therefore, in assembly work a tactile sensor and a compliance device must be used which can compensate for or absorb the relative positional error between the robot and workpieces. (Edited author abstract) 7 refs.

Asakawa, Kazuo (Fujitsu Lab Ltd, Kawasaki, Jpn). *Adv Rob* v 1 n 1 1986 p 59-69.

**090722 AUTOMATION A MUST FOR HYBRID SYSTEMS.** Within the past several years, many electronics manufacturers have been experiencing both increased competition and demands to reduce overall manufacturing time. A changeover to automated production can be expensive and time consuming in terms of system development and implementation. It can also be a factor in personnel realignment or reduction, an item important to both management and labor. Major considerations such as these should be thoroughly explored before investing thousands of dollars in development and implementation of an automated Surface Mounted Component (SMC)

System. A description is given of the development of a Surface Mounted Component (SMC) system to be used in the assembly operations of Northern Telecom.

Anon. *Rob World* v 4 n 9 Aug 1986 p 24-25.

**090723 DEVELOPMENT OF ROBOTS FOR AUTOMATIC ASSEMBLY OF BOLTED SEGMENTS.** In order to conserve labor, to complete shield tunnel excavation work in a shorter period, and to improve safety, an automatic assembly robot system has been developed. An experimental assembly system for ordinary bolted concrete segments (3.55 m in diameter) has been thoroughly tested to confirm that these segments can be fed and assembled automatically. To align the bolt holes of the segments, the position of the already assembled segment is sensed by means of various position sensors incorporated in the robot, and IHI-made hydraulic stepping cylinders are employed for position control. The segments can be assembled automatically at a rate of one ring every 25 minutes. (Edited author abstract)

Yanagi, Yoshio (IHI, Tokyo, Jpn); Takayama, Seiji; Ohtsuka, Ryuzaburo. *IHI Eng Rev (Engl Ed)* v 19 n 4 Oct 1986 p 158-163.

**090724 FLEXIBILITY HELPS TO MEET EUROPEAN MARKET DEMANDS.** The Italian company Axis has built a robotic line for a domestic appliance manufacturer, OEP. The motor assembly line has been built for use in a domestic vacuum cleaner. It takes armatures and stators manufactured on Axis machines and builds them into a complete electric motor of two basic types - A41 and A42. The line is divided into two sections: the first assembling the motor and the second building on the cooling fan. Both sections use the Bosch pallet transport system to carry components on standard pallets. Insertion is carried out either by pick-and-place units or Bosch SCARA SR 800 robots. Each working station operates independently under its own micro-processor control.

Rooks, Brian. *Assem Autom* v 8 n 1 Feb 1988 p 17-21.

**090725 PRECISION, FORCE AND FLEXIBILITY - THE SECRETS OF ROBOTIC ASSEMBLY.** From their first venture, an industrial consultancy service known as COD Inter Techniques, Georges Martin and Laslo Horvath now own a group of five companies, one of which markets their own design of robot, and another which designs and markets flexible assembly systems. In 1984, the two men set up Cybro, the company which would market the robots. The following year, they set up the Sysmo company to take care of flexible assembly systems. Sysmo developed its own flexible transfer system, Sysmove, which is an integral part of the flexible assembly solutions. As well as COD, Cybro and Sysmo, the group also includes Sitelec for industrial electronics and vision systems, and Hormar Holding for management, innovation and industrial computerization. These systems are briefly described.

Kochan, Anna. *Assem Autom* v 8 n 1 Feb 1988 p 23-25.

**090726 TRANSMISSION BELT PRODUCTION BREAKS SOME NEW GROUND.** Van Doorne Transmissie (VDT) in Holland has lifted the lid on the production facility for the steel belt of its continuously-variable transmission (CVT) where robots have a critical role. Portal-type machines of VDT's own design and make are used at an exacting stage of a unique manufacturing process that breaks new ground in computerized metal-forming and assembly operations. The belt consists of an endless train of 300 individual vee-blocks aligned and supported by a parallel pair of laminated loops. It is hydraulically clamped between the input and output pulleys, and works in compression rather than tension to transmit power. Each of the twin loops forming the VDT belt comprises 10 rings of steel sheet fitted together concentrically. Like a multi-strand cable, this assembly combines flexibility and strength with durability.

Scott, David. *Assem Autom* v 8 n 1 Feb 1988 p 26-28.

**090727 DESIGN SPECIFICATION OF PARTS DIMENSIONAL TOLERANCE FOR ROBOTIC ASSEMBLY.** Success of robotic assembly can be limited by parts dimensional tolerances as well as robot repeatability. This paper examines the effects of these limitations on the success (or failure) of parts assembly. A Positioning Design Factor for Assembly (PDFA) is defined to represent the percentage of all cases where the combination of parts dimensional tolerances and parts positioning errors result in positive effective clearance, which is one of the conditions leading to successful assembly. Mathematical derivations have been applied to the classical peg-in-hole problem. A Monte Carlo analysis was used to predict the probability of favourable positioning conditions for successful insertions. The simulation also incorporated several common assembly situations such as the effect of chamfers on the mating parts and the ANSI Standard fit classes. (Edited author abstract) 10 refs.

**090728 ENGINE PARTS ASSEMBLY LINE ADOPTS ROBOTS WITH 6 DEGREES OF FREEDOM.** Kawasaki Heavy Industries has established a comprehensive organization for promoting system automation that goes far beyond the robots themselves. The automated line built by Kawasaki Heavy Industries is not completely unmanned; the capabilities of the robots are fully exploited in an arrangement that maintains a suitable harmony between them and the human workers. The article introduces the major features of the assembly lines that the company has set up for compact engine parts. These are: flywheel attachment station; fixed-quantity lubrication and labeling station; system for applying anticorrosive coating to transmission parts.

Anon. *Trade Times* 424 Mar 1 1988 p 12-13.

**090729 FITTING OF CRIMP CONTACTS TO CONNECTORS USING INDUSTRIAL ROBOTS SUPPORTED BY VIBRATING TOOLS.** When fitting contacts to connectors, the flexibility of the wires and the irregularity of the contact shapes have proved to be the greatest obstacles in developing automation. Within the framework of the present project, two methods for fitting irregular and flexible parts have been developed, both using industrial robots supported by vibrating tools. For theoretical analysis the irregular, flexible part is mathematically idealized. The tests are carried out with these idealized parts and crimp contacts. These tests proved that the vibration method is suitable for fitting irregular, flexible parts. (Author abstract) 2 refs.

Warnecke, H.J. (Fraunhofer-Inst fuer Produktionstechnik & Automatisierung, Stuttgart, West Ger); Frankenhauser, B.; Gweon, D.G.; Cho, H.S. *Robotica* v 6 pt 2 Apr-Jun 1988 p 123-129.

**090730 UNTERSUCHUNGEN UEBER DIE AUTOMATISCHE MONTAGE VON SCHLAEUCHEN MIT INDUSTRIEROBOTTERN.** [Studies of the Automatic Assembly of Hoses by Industrial Robots]. As a result of certain obstacles to automation, such as the lack of rigidity and the large tolerances of the workpieces, assembly of hoses has so far proved impossible. Fundamental tests were carried out on both the assembly process and the grip process, as well as quantitative and qualitative tests on the chosen assembly parameters. In addition, methods and the influence parameters acting on them as tolerance compensation are described. Examples are given of designs of the base parts and joining parts which are suitable for assembly. For the assembly of a chosen combination of joining parts and base parts a pilot assembly cell was set up with industrial robots and its feasibility was established. (Author abstract). 3 Refs. ## Computer Aided Design

**090732 FRAMEWORK FOR CAD-BASED GEOMETRIC REASONING FOR ROBOT ASSEMBLY LANGUAGE.** In this paper, we present a framework for reasoning about objects based on their shapes and features and the representation of such objects for robotic assembly planning when the modelling is done on a computer aided design (CAD) system. We show the importance of AI languages in the communication of constructive solid geometry (CSG) based information from modellers. Finally, we present the schematic for a formalism, based on Prolog, for expressing object properties and assembly situations. (Edited author abstract) 38 refs.

Nnaji, Bartholomew, O (Univ of Massachusetts, Amherst, MA, USA). *Int J Prod Res* v 26 n 5 May 1988 p 735-764.

**090733 FORMAL APPROACH TO SPECIFYING ASSEMBLY OPERATIONS.** Experience has proved that exploiting robots for assembly tasks is much more difficult than manufacturing engineers had expected and many attempts at implementing robotic assembly have failed. The authors research has led them to believe that a formal approach to specifying the steps required for assembly would be of great benefit in developing the required software for a specific task, and in adaptively controlling and monitoring the execution of robotic assembly steps. The US National Bureau of Standards has developed a formal system, called ABC (for Assembly By Constraints) for specifying the steps required for assembly. The system is based on the reduction in the degrees of freedom of objects as they are assembled. Using this basic concept, the authors have developed 14 primitive operations which can be used to completely specify assembly steps for a large class of problems. This paper initially outlines the historical development of the system, then describes two pieces of software developed to allow easy definition of assembly tasks using the ABC system, and finally presents two practical examples. (Edited author abstract). 27 Refs.

**090734 SCHEMA FOR CAD-BASED ROBOT ASSEMBLY TASK PLANNING FOR CSG-MODELED OBJECTS.** This paper describes a robot assembly task planner that processes the knowledge of the working environment and generates a sequence of general or robot independent commands. By means of acquiring the world knowledge from the CAD systems and generating these commands, a robot should be able to automatically perform the task. The reasoning behind the decomposition from task level to mid level, and from the mid level to the general robot level planning is developed. The mathematical expressions which allow for the relating of assembly situations to the individually generated subtasks and consequent proofs of the effect of such statements are discussed. (Edited author abstract). 22 Refs.

Nnaji, Bartholomew O. (Univ of Massachusetts, Amherst, MA, USA); Chu, Jau-Yen; Akrep, Michael. *J Manuf Syst* v 7 n 2 1988 p 131-145.

**090735 SIMPLIFIED GENERATION OF ALL MECHANICAL ASSEMBLY SEQUENCES.** A modification of A. Bourjault's method (1984) for generating all valid assembly sequences for the set of parts that constitute an assembly is presented which makes practical the applications of this technique of assembly analysis to assemblies with greatly increased part count. The difference between the two methods is in the form and number of the questions whose answers yield the relations that allow algorithmic generation of assembly sequences. Bourjault's method requires  $2l^2$  questions plus an often larger number of subsequent questions whose existence depends on answers to part of the former question set; all have yes or no answers. (Here  $l$  is the number of relations between parts). The modified method requires  $2l$  questions that are answered in a precedence-logical form. The questions are similar to those asked by an engineer contemplating assembly of a set of parts. Applications and techniques for use are presented, and examples are shown for  $l$  as great as 18. 7 refs.

## Computer Interfaces

**090736 ONE FOR THE HEART.** Data-driven robotic assembly at Hewlett-Packard's plant is presented that produces five circuit board models, four of which are double-sided, for a total of nine different images. These nine images require over 550 discrete component placements. Further, work in the plant is based on demand-pull (JIT) production. One robotic assembler accurately accommodates a variety of placement demands without requiring constant reprogramming and system setup. The host-computer program contains a database file comprising CAD data for each component and the assembly sequence for each circuit board image. The robot controller in turn contains the feeder locations and tool change locations, enabling it to respond accurately and quickly to the information sent from the host.

**Control** See Also ELECTRONICS ENGINEERING—Education; PRINTED CIRCUITS—Robotic Assembly; ROBOTS, INDUSTRIAL—Control.

**090737 FRAMEWORK FOR INTELLIGENT ASSEMBLY IN INDUSTRY.** A special tool for using robots in intelligent industrial assembly is presented. The semantic network is the model for knowledge base organization. Planning is done by means of a special kind of production rules named demons. A dedicated NON-VON machine GRAM (GRAM Machine) stands at the basis of intelligent robot programming. Finally an example of using GRAM in industrial assembly is discussed. (Author abstract) 6 refs.

Mandutianu, Dan (Inst for Computer Technique & Informatic, Bucharest, Rom); Voinea, Serban. *Int J Prod Res* v 26 n 4 Apr 1988 p 599-611.

## Costs

**090738 NEXT STAGE IN THE USE OF ROBOTS FOR ASSEMBLY.** For single-station robot assembly, steps are already being taken to address the need for fast reconfigurability, low operator involvement and minimal equipment dedicated to specific parts or products. With standard serial assembly, however, the special equipment costs are still often too high to allow the economic assembly of products with total production volumes of less than 50,000 units and unfortunately many products are manufactured with volumes smaller than this. It becomes necessary therefore to reduce the effective cost of the re-usable equipment. Ways of doing this are discussed in this paper. (Edited author abstract). 6 Refs.

Redford, A.H. (Univ of Salford, Salford, Engl). *Int J Mach Tools Manuf* v 28 n 3 1988 p 273-279.

## Education

**090739 LABORATORY EXPERIMENT TO TEACH SOME CONCEPTS ON SENSOR-BASED ROBOT ASSEMBLY SYSTEMS.** A laboratory experiment is described that can be performed by electrical engineering graduate students and senior undergraduates. The experiment involves the assembly of a diesel-engine oil pump with an IBM RS-1 robot. The robot is instrumented with a force-sensing gripper and an optical binary sensor to detect parts in the gripper. A GE Optimation binary vision system is also used to monitor the manipulator workspace through a charge-coupled device (CCD) camera mounted on the robot arm. The students are required to program the manipulator and to process the information from the various sensors, which are used to recognize assembly components and to verify assembly operations in real-time. This assembly experiment is designed to familiarize electrical engineering students with the problems which dominate robot-based assembly systems and to demonstrate a number of practical sensor-based motion strategies which can overcome part and robot positional uncertainty found in typical manufacturing environments. These sensor-based motion strategies improve the reliability of a robot assembly system. The sensor-based assembly experiment, the laboratory setup, and the sensor-based motion strategies are discussed in detail. 33 refs.

France See ASSEMBLY MACHINES—Automation.

## Industrial Applications

**090740 APPLICATION OF ROBOTS IN ASSEMBLY AUTOMATION.** The development of flexible assembly is closely related to the introduction of robots in assembly automation. It has long been recognized that automatic parts assembly by robots is one of the most delicate and most difficult tasks in industrial robotics. This task involves two control problems: trajectory planning for the whole automatic assembly process and reduction of the reaction forces appearing between the parts being assembled. This paper addresses both aspects of this control task. The strategical control level for the manipulation of robots and various approaches to trajectory planning tasks in assembly processes are discussed. A new approach to the determination of the strategical control level, including various models (geometric, kinematic and dynamic) for manipulation robots, is briefly described. The last and most delicate phase of the assembly process is parts mating, which is rather like inserting a peg in a hole. The experimental results of the industrial robot insertion process with force feedback are also presented in the paper. (Edited author abstract) 20 refs.

Vukobratovic, M. (Inst 'Mihajlo Pupin', Belgrade, Yugoslavia); Stokic, D. *Rob Comput Integr Manuf* v 4 n 1-2 1988, Manuf Sci, Technol and Syst of the Future, Ljubljana, Yugosl, Sep 12-14 1985 p 175-180.

## Laser Applications

**090741 LASER APPLICATIONS FOR SMALL PART ASSEMBLY.** With the development of the fiber-glass-based laser light-cable technology it is now possible to use one source of radiation for integrating several welding places in an assembly machine. Also with the small-sized focusing optics, from 25mm in diameter and 150mm long, now coming into use, it is easier, as compared with the integration of a complete source of radiation, to use laser welding also in the limited confined space of stations in an automatic assembly machine. Another problem in automatic assembly can be the marking of products and the inscription of running numbers of products or the date of manufacture. This problem can be solved by microprocessor-controlled solid-state laser units. The possibility of contactless welding, inscribing or processing can widen the scope of automation in electro- and small parts assembly. 2 refs.

feld, West Ger). *Assem Autom* v 7 n 3 Aug 1987 p 133-136.

**Mathematical Models** See Also PROBABILITY—Queueing Theory.

**090742 OPERATIONS CHOICE FOR THE ROBOT IN ASSEMBLY SYSTEMS.** The problem of the choice of operations for a robot in an assembly system was formulated mathematically as the discrete stochastic system control problem. Decomposed algorithms which have been considered recognized first the current state of the assembly process and basing on it they chose the assembly operation. To control such assembly processes several state recognition algorithms were proposed and applied. The situation where a priori knowledge about the process is lacking was considered and estimates assuring the convergence of appropriate algorithms were proposed. Simulations results based on different algorithms of the choice of operations for a robot have been compared. (Author abstract) 15 refs.

**Planning** See ARTIFICIAL INTELLIGENCE—Expert Systems.

## Productivity

**090743 MAXIMIZING ROBOT PRODUCTION RATES FOR SIMPLE INSERTION OPERATIONS.** In the application of a robot to any process requiring component insertions, one must consider the ability of the robot to attain consistent part insertions given its inherent variability and the dimensional tolerances of the mating components. For some combinations of robot repeatability and component tolerances, failure at insertion is expected to occur with frequencies that can be determined analytically. Given this condition, it is important to be able to determine the point at which the robot should cease attempting to insert a particular component or set of components, given a prior sequence of failed attempts. In this paper the structure of the problem is analyzed and formulas for determining stopping rules are derived. We focus on the case of chamferless insertions, where there are no lead-ins to assist in centering the part. (Author abstract) 19 refs.

**090747 KINEMATIC EQUATIONS AND SOLUTIONS OF A HUMAN-ARM-LIKE ROBOT MANIPULATOR.** For prosthetic arms and also for the next generation of robots, mechanical manipulators consisting of links articulated in a way that better duplicate a human arm structure will be used. To control such an arm, the inverse kinematic equations, necessarily, have to be solved. There is no general formula efficient enough to solve these non-linear equations, and for each particular arm-wrist combination, a specific solution has to be sought according to the arrangement of the arm links and the type of wrist. This paper presents solutions for a human-arm-like manipulator with 6 degrees of freedom. The approach is mainly an analytic geometry method and proposes a new way of tackling the inverse kinematic problem. (Author abstract) 19 refs.

Hemami, Ahmad (Concordia Univ, Montreal, Que, Can); Labonville, Rejean. *Robotics* v 4 n 1 Mar 1988 p 65-72.

**090748 CALIBRATION OF ROBOT WRIST FORCE SENSOR.** Force feedback is one of the important feedbacks in robot control. The wrist force sensor located between the gripper and the arm is considered to be the most important force sensor. The calibration of the wrist force sensor is the same as finding its C matrix. The authors suggest a method for finding the C matrix and point out that the calibration methods of B.E. Shimino and RTI are mathematically wrong. The authors design an experiment to verify their idea. The experiment shows that the authors' result is close to the applied load and RTI's result is quite different from the applied load. The authors offer another simplified method to find  $6 \times 6$  C matrix. The result from the  $6 \times 8$  C matrix. (Edited author abstract) 7 refs.

**090749 BASIC STUDY ON A WALL CLIMBING ROBOT (I) -MOVING METHOD AND SAFETY.** There is a great need for the development of a robot which can perform dangerous tasks such as the painting and cleaning of high rise buildings, tanks and so on. A wall climbing robot (MEL-SPIDER) which can move on vertical walls, has been developed. The robot has two parts, a mobile SPIDER which walks on the walls, and a power/control unit which is situated on the ground. The unit supplies power and control signals to the SPIDER through pneumatic tubes and electric cables. The SPIDER has eight legs and each leg is terminated with a vacuum suction cup. We have investigated the walking capabilities of the SPIDER, and have shown that it is capable of moving stably and reliably up and down, as well as sideways, on vertical walls. We have also discussed ways of improving the safety of the SPIDER. (Edited author abstract). 9 Refs. In Japanese.

**090752 PROCEEDINGS OF ROBEXS '87 THIRD ANNUAL WORKSHOP ON ROBOTICS AND EXPERT SYSTEMS.** This conference proceedings contains 43 papers discussing recent advances in the field of robotics and artificial intelligence. The robotics sessions focus on modeling and planning, AI methods in robotics, system aspects of robotics, and robotic control. The expert systems sessions cover methodology, practices, goals, medical applications, automation planning, and systems dealing with real-time problems. The key theme sessions include CIM and flexible manufacturing methods, robotics and manufacturing applications, CAD/CAM and integration, AI design automation and stochastic and simulation methods. One session deals with computer algebra and S/W automation. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10945 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**090756 ROBOTICS RESEARCH: THIRD INTERNATIONAL SYMPOSIUM (MIT PRESS SERIES IN ARTIFICIAL INTELLIGENCE).** This symposium proceedings contains 48 papers on various aspects of robotics research. The papers are grouped into four main sections: Perception, Decision, Action, and Systems. The Perception section is divided into two chapters, the first on stereo and motion and the second on object identification and modeling. The first chapter of the section on Decision is on the topic of planning and reasoning and emphasizes the general aspects of intelligent decision making; the second chapter, entitled Task Level, is concerned with more specific aspects. The Action section has three chapters. The first is on kinematics and dynamics, the second on control, and the third on design and mechanisms. Making up the final section, on Systems, are, first, a chapter on the strongly emerging field of mobile robots and, second, a chapter on integrated systems. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11592 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

## Analysis

**090757 EFFECT OF JOINT MOTION CONSTRAINTS ON THE WORKSPACE AND NUMBER OF CONFIGURATIONS OF MANIPULATORS.** A method for the investigation of the effect of joint motion constraints on the workspace and its subspaces with different number of configuration is developed. The method is also helpful in choosing the location and extent of the applied limitations to the motion at the joints, and in the design of manipulators with desired workspace and number of configurations. As examples, the effect of constraints on the workspace, subspaces, and number of configurations of a 3 R and 3 RPR manipulators are studied. (Author abstract) 18 refs.

**090758 INVESTIGATION INTO THE COMPLIANCE OF SCARA ROBOTS. PART I: ANALYTICAL MODEL.** A special class of robots suited for assembly tasks called SCARA (Selective Compliance Assembly Robot Arm) provides a degree of built-in flexibility due to robot structure. In such robots there are three revolute joints and a prismatic joint. They offer four degrees of freedom consisting of rotation about two vertical and parallel axes at the revolute joints, and translation and rotation about the tool axis. A mathematical model which expresses the end effector deflection as a function of the robot Jacobian and the drive compliance parameters in Cartesian coordinates has been developed. The modified generalized assembly force model developed for the Selective Compliance Assembly Robot Arms (SCARA), used in this investigation, is described. Constraints required to prevent jamming and wedging of parts during assembly are outlined. (Edited author abstract) 13 refs.

**090759 INVESTIGATION INTO THE COMPLIANCE OF SCARA ROBOTS. PART II: EXPERIMENTAL AND NUMERICAL VALIDATION.** A model of inherent elastic compliance was developed for general position-controlled SCARA, with conventional joint feedback control, for both rotational and prismatic part insertion (Part I). The developed model was applied to the SKILAM and ADEPT I robots for validation. Experimental procedures and numerical solution methods are described. It was found that the ADEPT I robot employs a coupled control strategy between joints one and two which produces a constant, decoupled end effector compliance. The applicable compliance matrix, in this case, is presented and the experimental results are discussed. The model may be used to develop compliance maps that define the amount of end effector compliance, as a function of the joints compliance, as well as its variation for different robot configurations. This is illustrated using data for the SKILAM SCARA robot. Results are plotted and discussed. (Edited author abstract) 10 refs.

ElMaraghy, H.A. (McMaster Univ, Hamilton, Ont, Can); Johns, B. *J Dyn Syst Meas Control Trans ASME* v 110 n 1 Mar 1988 p 23-30.

**090760 METHOD FOR DETERMINING AND CORRECTING ROBOT POSITION AND ORIENTATION ERRORS DUE TO MANUFACTURING.** A method is presented for calibration of a robot to correct position and orientation errors due to manufacturing. The method is based on the shape matrix robot kinematic description. Each joint is individually and successively moved in order to explicitly calculate the shape matrix of each link. In addition, methods to correct for the errors in both the forward and inverse kinematic solutions are presented. The modification of the forward solution is a simple task. The modification of the inverse kinematic solution is a difficult problem and is achieved by an iterative technique which supplements the closed-form solution. An example of the calibration and inverse solution is presented to show the improvement in the accuracy of the robot. (Author abstract) 16 refs.

**090761 ON-LINE ROBOT TRAJECTORY CONTROL IN JOIN COORDINATES BY MEANS OF IMPOSED ACCELERATION PROFILES.** A method for trajectory control in the joint space is presented. An acceleration profile is proposed for each segment of the trajectory. After a twofold integration a position trajectory is obtained with advantageous characteristics. The position trajectory is completely dynamically balanced; it exhibits continuity up to the third derivative of the position. This way, minimum requirements are imposed on the actuators. The technique delivers predictable results since the trajectory deviates only slightly from a straight line connection between successive joint coordi-

nates. Very limited computational effort is required. (Author abstract). 10 Refs.

**090762 DYNAMIC ANALYSIS OF A THREE-DEGREES-OF-FREEDOM IN-PARALLEL ACTUATED MANIPULATOR.** The dynamic analysis of a three-degrees-of-freedom in-parallel actuated manipulator is presented. The equations of motion have been formulated in joint-space using the Lagrangian approach. The analysis provides the solution to predict the forces required to actuate the links so that the manipulator follows a predetermined trajectory. A dynamic simulation program illustrates the influence of the link dynamics on the actuating force required. An example of tracing a helical path is chosen to illustrate the dynamic simulation and to show that the Cartesian position of the moving platform may be controlled at a sacrifice of orientation freedoms. The dynamic analysis provides a basis for future theoretical research to develop the control scheme, for experimental research to estimate the inertia parameters, and for design optimization of the prototype manipulator. 18 refs.

**090763 FEASIBILITY STUDY OF A ROBOT MANIPULATOR FOR THE DISABLED.** A robotic manipulator system appears to offer much potential for a severely handicapped person who has little or no hand function. Existing environmental control systems fulfil an important role, but are limited to preselected tasks. The robotic system described here aims to overcome such limitations by providing a user-controlled manipulative device, which is not restricted to preselected tasks. The paper describes the development of a system based on a relatively cheap desk-top mounted robotic device controlled by a microcomputer, in order to investigate the feasibility of such a system. The problems which have been encountered are the provision of user input commands from a person with limited control function, and also the progression from general control of the robot to the performing of useful domestic tasks. The paper also describes and discusses the results of a user survey and user trials. (Author abstract) 5 refs.

**090764 SOLVING DISK CERTIFICATION PROBLEMS WITH A ROBOTIC WORKCELL.** Testing is typically the last process performed on a rigid disk before it is installed in a disk drive. Defects and errors introduced during the testing process are usually detected only after the disk is installed; the cost of mistakes is therefore many times that of the disk itself. Simple timing studies sometimes indicate that automated disk certification does not increase overall throughput. The DC Series disk certification workcell was developed for automated burnishing, glide testing, and certifying of 5-1/4 in. and 3-1/2 in. rigid disks. Cell components are an Intellex Model 605 or IBM Model 7545-800S robot with an Applied Robotic Technologies end effector, Fluoroware cassettes, and an IBM/PC XT or AT controller. Some manufacturers have gone offshore to reduce labor costs only to find that increased inventory and additional freight costs and duty plus the labor and current stability in a foreign country can offset anticipated savings. Robotics addresses the problem of high labor costs and offer the additional advantages of rapid local response to technical issues and potentially greater savings through improved quality and yield. The benefits of using the DC Series Disk Certification workcell are discussed. (Edited author abstract)

**090767 COMPUTER-ASSISTED CHOICE OF ELECTROHYDRAULIC SERVOSYSTEMS FOR MANIPULATION ROBOTS USING COMPLETE MATHEMATICAL MODELS.** In this paper, a computer procedure for the choice of electrohydraulic servosystems of manipulation robots is described. Mathematical models based on this procedure represent complete dynamic models of manipulation robots where all dynamic effects are included. Two types of mathematical model of electrohydraulic servosystems are considered: a linearized mathematical model with fixed parameters (time-invariant model) and a linearized mathematical model with variable parameters (time-varying model). Based on exact dynamic analysis, interactive procedures for optimal choice of electrohydraulic actuators, using both types of mathematical models are derived. A criterion is based on the minimum energy consumption for trajectory realization. Selection procedures are given on a typical example of manipulation robot. Also, programmed control calculated using both types of linearized models is compared with programmed control using exact nonlinear models of servosystems. It is shown that the linearized model with variable parameters represents qualitative dynamic behavior of manipulation robots. (Author abstract) 6 refs.

**090768 ORGANIZING CUSTOMIZED ROBOT DYNAMICS ALGORITHMS FOR EFFICIENT NUMERICAL EVALUATION.** In 1983, the computer program called algebraic robot modeler (ARM) was implemented to generate symbolically complete closed-form and recursive dynamic robot models. To enhance computational efficiency for dynamic simulation and real-time control, the systematic organization of these symbolic models was introduced in 1985 to remove repetitive calculations within and across equations and thereby generate customized robot dynamics algorithms. The systematic organization procedure of ARM is detailed and its performance compared with documented organizations. It is pointed out that the systematic

organization procedure, and the exploitation of kinematic and dynamic manipulator structures through symbolic modeling, make ARM-generated customized algorithms the most computationally efficient manipulator dynamics algorithms of those compared. 32 refs.

**090773 INTERACTIVE ROBOT SIMULATOR FOR HIGH-LEVEL TASKS.** A robot simulator is developed that enables a robot operator to make plans of high-level tasks easily without knowing the details of the robot, before its off line teaching and programming. The simulator is based on the structural model developed in the CAD system Himades-1, which was devised for general assembly units with rotating and prismatic pairs. First, some unique basic functions that use the structural model are introduced. Then the general method, independent of the type of robot, is reported, which provides the consistent and intelligent algorithm to extract the necessary transformation matrices systematically from the structural model, to set up automatically the formulas for backward motion analysis and to solve them. (Edited author abstract) 9 refs.

**090774 MAXIMAL DISTANCE FOR ROBOTIC SIMULATION: THE CONVEX CASE.** Given two hyper-rectangles in  $E^n$  with sides having surface normals in the directions of the axes, each containing a set that touches all  $2n$  sides of its containing hyper-rectangle, it is important to have an easily calculated upper bound on the distance between the sets, for use in a branch and bound algorithm applicable in collision avoidance in robotic simulation. In a previous paper, such a bound was given under the hypothesis that the sets are connected. Here, the authors consider the case where the sets are convex. (Author abstract) 4 refs.

Andersson, L.E. (Univ of Linköping, Linköping, Sweden); Stewart, N.F. *J Optim Theory Appl* v 57 n 2 May 1988 p 215-222.

**090775 PHYSICALLY BASED SIMULATION MODEL FOR ACOUSTIC SENSOR ROBOT NAVIGATION.** A computer model is described that combines concepts from the fields of acoustics, linear system theory, and digital signal processing to simulate an acoustic sensor navigation system using time-of-flight ranging. By separating the transmitter/receiver into separate components and assuming mirror-like reflectors, closed-form solutions for the reflection from corners, edges, and walls are determined as a function of transducer size, location, and orientation. A floor plan consisting of corners, walls, and edges is efficiently encoded to indicate which of these elements contribute to a particular pulse-echo response. Sonar maps produced by transducers having different resonant frequencies and transmitted pulse waveforms can then be simulated efficiently. Examples of simulated sonar maps of two floor plans illustrate the performance of the model. Actual sonar maps are presented to verify the simulation results. 9 refs.

**090776 COMBINED OBSERVER-CONTROLLER SYNTHESIS FOR UNCERTAIN DYNAMICAL SYSTEMS WITH APPLICATIONS.** Control of a class of nonlinear/uncertain systems is discussed using a variable-structure systems (VSS) approach. Observations of the states of such systems is also considered. The natural extension to an observer-controller design is illustrated using a computer simulation example of a  $\theta$ - $r$  manipulator. Next, the problem of path planning is addressed using a combined observer-controller strategy. The aspects of hardware implementation of the proposed observer-controller are then analyzed. 34 refs.

**Control** See Also CONTROL SYSTEMS—Robustness.

**090777 NONLINEAR ADAPTIVE CONTROL OF AN N-LINK ROBOT WITH UNKNOWN LOAD.** An N-link planar robot holding an unknown load and driving

its end-effector along a prespecified trajectory is studied. The effect of the unknown load is discussed, and the nonlinear dynamic equation with the unknown load is derived. A non-linear model-reference adaptive control algorithm is developed for tracking of a trajectory that is a piecewise continuous function of time. The tracking error dynamics represent a linear stable system with persistent disturbances, and the Germaidze-Krasovskii theorem in the Lyapunov second method is applied to show the error stability. Digital computer simulations show the effectiveness of the adaptive control algorithm for the unknown load with mass 2 kg, 5 kg, and 10 kg. The effect of the computation time delay on the system dynamics is also addressed. (Author abstract) 22 refs.

**090779 MULTIPROCESSOR SYSTEM FOR REAL-TIME ROBOTIC CONTROL.** SIERA (System for Implementing and Evaluating Robotic Algorithms) is a multiprocessor system that incorporates a tightly coupled bus-based system (the Real Time Servo System, or RTSS) and a loosely coupled link-oriented network (the Armstrong Multiprocessor System). SIERA is capable of controlling many types of commercially available robots because the modular construction of its hardware and software has minimized robot dependencies. Support routines have been created to yield a powerful robotic algorithm development system. This includes a custom real-time operating system for the RTSS and special processes for the Armstrong system. These facilities allow a researcher to interactively modify or replace any algorithm related to the operation of the robot. A compliant control example is used to illustrate SIERA's capabilities. The algorithm presented in this example may be applied to unconstrained motion as well as compliant motion, and is the topic of further research. (Edited author abstract) 18 refs.

**090780 EXPERIMENTS WITH THE USE OF A RULE-BASED SELF-ORGANISING CONTROLLER FOR ROBOTICS APPLICATIONS.** The Rule-Based Self-Organising Controller (SOC) has as one of its main advantages the fact that there is no need to have a mathematical description of the system to be controlled. In this controller, the rules are linguistic statements expressed mathematically through the concepts of Fuzzy Sets and correspond to the actions a human operator would take when controlling a given process. This paper describes several experiments which were performed with SOC. The control was considered of both simulated linear and non-linear processes. The performance of the controller was investigated for step inputs as well as for waveforms which the process output had to track; the effect of process noise was also considered. It was shown that SOC had a performance slightly superior to that of a PID controller when noise was present and the process had time varying coefficients as well as pronounced non-linear characteristics. This paper also reviews some of

the successful initial work carried out in connection with the application of SOC to a revolute joint robot arm. (Edited author abstract) 19 refs.

**090782 ROBOT CONTROL USING ADAPTIVE TRANSFORMATIONS.** A control strategy is presented for robots that do not have accurately known mechanical structures or have inaccuracies caused by bending, slip, or backlash. In the system, the manipulator's endpoint is monitored in a servo loop, so that inaccuracies in the structure can be compensated. An adaptive transformation from task to robot-oriented coordinates has been used online, without prior modeling or calculation. The strategy developed has been simulated for a two-degree-of-freedom robot. Results are compared with those obtained using the inverse Jacobian as part of the control system. 14 refs.

**090783 ROBOT CONTROL IN THE NEIGHBORHOOD OF SINGULAR POINTS.** An alternative method is proposed for designing a robot-controller in Cartesian coordinates using a time-scale transformation. The proposed controller achieves slow poles in the area of poor manipulative ability and fast poles in the area of good manipulative ability. Therefore, the robot can be properly controlled in the neighborhood of singular points without reducing the performance outside the neighborhood of these points. 14 refs.

**090784 PLANNING OF STRAIGHT LINE TRAJECTORY IN ROBOTICS USING INTERACTIVE COMPUTER GRAPHICS.** The planning of straight line trajectory using the interactive computer graphics simulation of robot manipulator movement is discussed. This new approach to straight line motion planning improves the 'bound deviation joint paths' developed by R.M. Taylor (1979). The new approach has three characteristics: (1) linear interpolation in joint space; (2) unequal intervals for interpolating knot points; (3) using interactive computer graphics to assure that the maximum deviation in the whole segment is less than the pre-specified values. The structure and mathematical basis of a computer program developed for this purpose are presented. (Author abstract) 10 refs.

**090785 CARTESIAN TRAJECTORY TRACKING FOR MANIPULATORS USING OPTIMAL CONTROL THEORY.** A Cartesian trajectory tracking system

for manipulators is developed using optimal control theory. By including the Cartesian position in the state vector, transformation of the trajectory from Cartesian space to manipulator joint space is avoided, and the Jacobian matrix need not be inverted. The tracking system may also be applied to kinematically redundant manipulators. For this type of manipulator, singularities are avoided by choosing a suitable performance index in the optimal control problem. Simulation using a simple kinematically redundant manipulator shows that a small tracking error can be achieved with low motor torques. (Author abstract) 11 refs.

Egeland, Olav (Norwegian Inst of Technology, Trondheim-NTH, Norw). *Model Ident Control* v 8 n 3 1987 p 137-147.

**090786 DYNAMIC CONTROL OF KINEMATICALLY REDUNDANT ROBOTIC MANIPULATORS.** We propose a control algorithm in which we are especially concerned with the manipulator dynamics. The algorithm is particularly well suited for the class of redundant manipulators consisting of a relatively small manipulator mounted on a larger positioning part. The main idea behind the algorithm is to augment the task space position vector by a set of generalized coordinates for the positioning part, so that the augmented task space position vector constitutes a set of generalized coordinates for the manipulator. In a simulation experiment, this control algorithm performed significantly better than controllers using generalized inverses of the manipulator Jacobian. (Edited author abstract) 15 refs.

**090787 COORDINATING CONTROL OF A SPECIAL JOINT STRUCTURE WITH MORE SERVOS THAN DEGREES OF FREEDOM.** A joint mechanism for use as a general building block in manipulators with a very high number of degrees of freedom is introduced. It consists of 3 servos driving a 2 d.o.f. universal joint by means of wire. A coordinate transformation set is developed, which includes positional, velocity and force transformations. Both direct and inverse transformations are presented. Special attention is given to the inverse force transformation which is obtained using linear optimization. The solution in this case is also shown to be valid for a more general class of constrained non-linear optimization problems. An example is given of the use of the coordinate transformation set; a joint control system including servos under internal force control. (Author abstract)

**090788 GAIT CONTROL SYSTEM OF A QUADRUPEL WALKING VEHICLE.** A walking vehicle has potential capability to be developed to an off-road machine with high mobility and adaptivity by using the coordination control of its multi-degrees of freedom. This paper discusses the gait control system based on a quadruped walking vehicle developed by the authors. The total structure of the control system, consisting of three levels named A, B and C, is clarified. The control algorithm of each level is studied in detail, particularly the three sub-systems belonging to level B, i.e. gait control in xy coordinates, the same in z coordinate and trajectory control of legs taking account up/down swinging. The control algorithm at level C, which regulates the basic reflex motions, is specifically discussed. Finally, these discussions are verified by walking experiments of a model TITAN III. The joystick control of omnidirectional motions and adaptive locomotion over irregular surfaces are successfully demonstrated. (Edited author abstract) 7 refs.

**090789 ROBOT CONTROL SYSTEM BASED ON FORTH.** For over 10 years, the National Bureau of Standards has conducted research in robotics. NBS has developed a Real-Time Control System (RCS) that uses the sensory-interactive hierarchical control model. RCS has been implemented by a small team of programmers and can control a variety of robots. Suggestions and theories detailing the needs of a fourth-generation robot controller have evolved from the implementation of RCS. The RCS software has been implemented with FORTH as its base coordinating and development system. Any number of programming languages can be used to solve the wide variety of problems associated with robotics, but some are better suited than others for certain tasks. The paper describes the RCS system reliability, and discusses RCS support tools. 7 refs.

**090790 NEW METHOD FOR THE ROBOT CONTROLLER DESIGN.** A new method to derive systematically control algorithms given exact linearization and decoupled controls of robots for manipulators is applied to simple examples. In particular, because this method does not require dynamical equations of mechanisms, its application to physical systems is a very simple operation. (Edited author abstract) 10 refs.

**090791 ROBOT-ARM-SYSTEM PLAYING 2 DIMENSIONAL PING-PONG GAME USING IMAGE PROCESSING TECHNIQUE.** A robot arm system equipped with a CCD camera and able to play a two-dimensional ping-pong game has been built. The system is able to play in the form of both robot versus robot and robot versus man. In the robot control part, 25 fuzzy production rules are used. Ambiguous instructions in terms of membership functions are generated by the robot itself using imagery data from a CCD camera. Each of these instructions consists of three fuzzy items. Two of them are input (ambiguous) information concerning the fuzzy point, that is, where the ball was hit, and the fuzzy angle, that is, from which direction the ball is coming, and the other is output information which shows how far the ball will reach. This output information, which also indicates the point the robot should move to, is calculated based on the fuzzy inference method. The whole system is controlled by only one 16-bit personal computer and works in real time. (Edited author abstract). 7 Refs. In Japanese.

**090792 COMPLIANT ROBOT MOTION I. A FORMALISM FOR SPECIFYING COMPLIANT MOTION TASKS.** A formalism is developed for specifying compliant motion tasks. It is based on the hybrid control functional specification method described by Mason. However, some new concepts are introduced: tracking directions, end-effector and task-frame motion constraints, feedforward velocity data, and task termination conditions. This formalism synthesizes all the information required in order to allow a completely automatic execution of the task. As a result, it achieves strict separation between programming and control, which is of primary importance for the integration of compliant motion into a robot programming language. Several examples show that the formalism applies to a broad class of compliant motion tasks. The newly defined tracking directions contribute to the autonomy of the robot control system in case only partial geometric information about the environment is available. (Author abstract). 24 Refs.

De Schutter, J. (Katholieke Univ Leuven, Louvain, Belg); Van Brussel, H. *Int J Rob Res* v 7 n 4 Aug 1988 p 3-17.

**090793 COMPLIANT ROBOT MOTION II. A CONTROL APPROACH BASED ON EXTERNAL CONTROL LOOPS.** A control approach for the execution of robot tasks in contact with the environment is worked out. The input to the controller consists of the task specification described in another paper. The control approach is based on external force and tracking loops, which are closed around the robot positioning system. The position control loops tend to decouple and linearize the complex robot dynamics, and therefore they present to the external controller a system which is easy to model and easy to control. Design and properties of external control loops are discussed in great detail. In particular, the role of a passive compliance with respect to task execution speed and disturbance rejection is analyzed both qualitatively and quantitatively. The resulting compliant motion controller has been tested experimentally, and proved to be very robust and to yield the theoretically expected performance. (Author abstract). 17 refs.

De Schutter, J. (Katholieke Univ Leuven, Heverlee, Belg); Van Brussel, H. *Int J Rob Res* v 7 n 4 Aug 1988 p 18-33.

**090794 TASK-SPACE TRACKING WITH REDUNDANT MANIPULATORS.** A controller for redundant manipulators with a small fast manipulator mounted on a positioning part has been developed. The controller distributes the fast motion to the small fast manipulator and the slow gross motion to the positioning part. A position reference is generated online to the positioning part to avoid singularities and the loss of degrees of freedom. The task-space position vector is augmented by the generalized coordinates of the positioning part. Feedback linearization and decoupling are then applied in the augmented task space to obtain a model consisting of decoupled double integrators. These integrators are controlled by linear quadratic optimal control. In the optimal control problem, the performance index is chosen so that the task-space position reference is tracked with a high bandwidth, while the reference to the positioning part is tracked with a low bandwidth. The controller has been applied to a simple planar redundant manipulator and an eight-link spray painting robot in simulation experiments. These simulations showed that a high bandwidth was possible with moderate actuator torques. 14 refs.

**090795 LANGUAGE-AIDED ROBOTIC TELEOPERATION SYSTEM (LARTS) FOR ADVANCED TELEOPERATION.** A language-aided robotic teleoperation system is described that incorporates two sets of teleoperational languages with a master-slave manipulator. One language offers flexible means, called software jigs, to specify motion constraints superimposed on operational motion, simplifying task motion. The other offers an easy method of teaching elementary tasks which frequently appear in teleoperation. Reexecution of the thus-taught program is effectively utilized. 7 refs.

**090796 MODEL PREDICTIVE HEURISTIC CONTROL OF A POSITION SERVO SYSTEM IN ROBOTICS APPLICATION.** A recently proposed method of control, namely model algorithmic control (MAC) or, equivalently, model predictive heuristic control (MPHC) is analyzed with a view to its implementation for the position control system. The formulation of the MPHC strategy to positional servo systems is presented. Both the regulator and the tracking problems are studied. The simulation and experimental results obtained indicate that the MPHC results in good performance, even under conditions of large time-varying changes in the parameters of the system. 3 refs.

**090798 INTERPROCESS COMMUNICATION FOR DISTRIBUTED ROBOTICS.** Because of the complex nature of the tasks performed by multiple robots cooperating in three-dimensional dynamic environments, centralized control is no longer practical; workcells have become centers of distributed computing. This motivates the need for an interprocess communication (IPC) facility which would integrate the individual elements both within and between workcells. A survey of IPC is presented in the context of distributed robotics. General approaches to communication within a distributed computing environment are discussed as an introduction to the overview of IPC. A discussion of the main IPC design issues for distributed robotics is included. 90 refs.

**090799 COORDINATION OF TWO PLANAR ROBOTS IN LIFTING.** The dynamic equations for a two-robot system with and without load are formulated. For control purposes, the constraint forces are derived as functions of input and state. The inverse plant method and computation of the constraint forces are used to coordinate the control of the system. No pressure or force sensors are considered, and no force feedback is used. The effectiveness of the control strategy for point-to-point motion of the coordinated robots performing a lifting task is checked by digital computer simulations. 27 refs.

**090800 CONTROL AND STABILIZATION OF NONLINEAR UNCERTAIN ELASTIC ROBOTIC ARM.** An approach is presented to the control of an uncertain nonlinear flexible robot arm (PUMA-type) with three rotational joints. The third link is assumed to be elastic. A torque control law, which is a function of the trajectory error, is derived for controlling the joint angles. The knowledge of the system dynamics is not required for the derivation of the controller. This controller includes a reference model to generate command joint angle trajectories, and a dynamic system in the feedback path which requires only joint angle and rate for feedback. The torque controller asymptotically decouples the elastic dynamics into two subsystems, representing the transverse vibration of the elastic link in two orthogonal planes. For the damping of the elastic vibration, a force control law using modal velocity feedback is synthesized. Simulation results are presented to show that the combination of the torque and force control law accomplishes reference joint angle trajectory tracking and elastic mode stabilization despite the uncertainty in the system. 25 refs.

## Design

**090801 OPTIMAL DESIGN OF ROTARY DYNAMIC ABSORBER FOR ROBOT.** The optimal design of a rotary dynamic absorber which is attached to an elastic robot is carried out in this paper. Based on the band-limited white noise base excitation, the optimal tuning and damping ratios of the absorber are determined by minimizing the variance of elastic robot response. The variable metric method used to determine those optimal

parameters for the variance cannot be calculated directly by integrating the transfer function over the band-limited frequency range. The effect of material damping of robot is small enough that it can be ignored. To have a small variance, the absorber must be installed away from the base and have the moment ratio  $\mu$  (defined as the ratio of mass moment of inertia of absorber to robot) greater than 0.03. (Author abstract) 10 refs.

**090804 BUILD BERT, THE BASIC EDUCATIONAL ROBOT TRAINER, PART 1.** The amount of training required in the applications of very simple robots, even commercially available ones is considered. A menu-driven, interactive control language is written that is intended to be simple enough to program a robot. A talking robot, called BERT, is designed that can be easily built with only commonly used electronics tools: a fine-tip soldering iron, wire cutters, pliers, and so on. To program the robot a device is needed capable of transmitting ASCII code at 300 baud, with 7 data bits, no parity, and 1 stop bit. In other words, almost any computer with a serial port, or a serial terminal itself, can be used.

**090805 GRAPHICAL SIMULATION OF PUMA ROBOT.** For students taking an introductory course in robotics it is at times difficult to visualize a robot in its different configurations. It would be helpful to them in the absence of a real robot, to be able to see and manipulate these positions on a computer screen. A software code using the DI3000 graphics package was developed for this purpose. The UNIMATION PUMA robot with three degrees of freedom (DOF) was modeled graphically in three dimensions so that given the co-ordinates of any

point in its work envelope the robot will be seen in a configuration necessary for reaching that point. (Author abstract) 3 refs.

**090806 INTRODUCING INDUSTRIAL ROBOTICS INTO AN UNDERGRADUATE AND POSTGRADUATE CURRICULUM.** The addition of the robot has caused several spin-offs to occur in the Mechanical Engineering department. Within the guidelines of the undergraduate curriculum a variety of experiments have been conducted on parts of the robot. The experiment is named 'the design of an experiment' and the ground rules are that we assign a set of students and they are supposed to design and implement an experiment to complete the task. This has been applied successfully to the robot and the results of some of the experiments involving the robot are reported. A brief description of a new robotics course, which has evolved because of the robot, is also given. Part of the research efforts that are a consequence of the new robot are also discussed. (Edited author abstract). 11 Refs.

## Elasticity

**090807 NONLINEAR OBSERVER FOR ELASTIC ROBOTS.** Robot manipulators in which the joints exhibit a certain amount of elasticity are discussed. The model of such robots is highly nonlinear, and available techniques to build nonlinear observers generally do not apply. A procedure to construct approximate nonlinear observers is proposed that uses a recent approach to deriving observers based on geometric nonlinear control theory together with an approximation technique. The conditions under which an exact observer exists are derived. Some examples are given for which simulation tests assure a good performance even when the observer is connected to a control system. 10 refs.

**090809 MAKING ROBOTS PAY OFF.** Rational evaluation is necessary in justifying robot applications in the plant. The article discusses four strategic factors that the evaluation should include. These are: basic applications fit; economic justification, both obvious and strategic; non-economic justification; and organizational environment check.

Brooks, Jake (Peat Marwick Main & Co, NY, USA). *Rob World* v 6 n 6 Aug 1988 p 13,14,16.

**090810 ROBOTICS: WHAT EVERY MANAGER SHOULD KNOW.** All manufacturing managers and executives should understand the basics of robotics before implementation takes place. When examining actual or proposed equipment in the plant, three aspects are addressed: its programmability; ability to operate unattended; the variety of tasks it can handle. Robots can be justified through four approaches: manufacturing necessity; economic payback; intangible benefits and future benefits. The group investigating robot applications should consider: the effect on workers displaced by robots; whether an adequate knowledge base exists to select,

design, install a robotic solution to a manufacturing problem; whether to choose a small pilot project for testing; who the working members of the robotic team will be; who would review the final recommendations.

**090816 DUAL-NUMBER TRANSFORMATION AND ITS APPLICATIONS TO ROBOTICS.** The dual-number line transformation (originally proposed by W.K. Clifford in 1873) is chosen for line representation in 3-D space. Lemmas and theorems indicating relevant properties of the dual number, dual vector, and dual matrix are proposed. This is followed by the transformation and manipulation of dual numbers for robotic applications. This transformation procedure offers an algorithm which deals with the symbolic analysis for both rotation and translation. In particular, it can effectively be used for direct determination of Jacobian matrices and their derivatives. It is shown that the proposed procedure simplifies the formulation of the robotic kinematics, dynamics, and control system modeling. 14 refs.

**090817 UNCERTAIN GEOMETRY IN ROBOTICS.** The author suggests that to operate efficiently, a robot system must be able to represent, account for, and reason about the effects of uncertainty in areas in which geometric analysis also plays an important part. He proposes that uncertainty be represented as an intrinsic part of all geometric descriptions. Toward this goal he develops a description of uncertain geometric features as families of parameterized functions together with a distribution function defined on the associated parameter vector. Uncertain points, curves, and surfaces are considered, and it is shown how they can be manipulated and transformed between coordinate frames in an efficient and consistent manner. The effectiveness of these techniques is demonstrated by application to the problem of developing maximal-information sensing strategies. 19 refs.

**090818 FEEDBACK STABILIZATION AND TRACKING OF CONSTRAINED ROBOTS.** Mathematical models for constrained robot dynamics, incorporating the effects of constraint forces required to maintain satisfaction of the constraints, are used to develop explicit conditions for stabilization and tracking using feedback. The control structure allows feedback of generalized robot displacements, velocities, and the constraint forces. Global conditions for tracking, based on a modified computed-torque controller and local conditions for feedback stabilization, using a linear controller, are presented. The framework is also used to investigate the closed-loop properties if there are force disturbances, dynamics in the force feedback loops, or uncertainty in the constraint functions. 31 refs.

**090819 DEVELOPMENT OF A FOUR-WHEELED MOBILE ROBOT SYSTEM FOR BEDRIDDEN PATIENTS.** With the aim of reducing the difficulties faced by handicapped people and those responsible for their care and nursing, we have undertaken research on the development of a four-wheeled mobile robot system to provide assistance in the daily activities of the bedridden and handicapped. The characteristics of this system are (1) front-wheel power steering and independently directly driven rear wheels, (2) one pair of manipulators which have nine degrees of freedom mounted on the four-wheeled mobile device, and (3) a hierarchical control system with one 16 bit and several 8 bit microcomputers. We utilize a teaching-playback method to develop control programs for specific activities. As a result of our research and development, we have succeeded in establishing fundamental techniques for mobile robot systems for bedridden patients. (Edited author abstract) 2 refs.

**090821 ADVANCED ROBOT SYSTEM FOR AUTOMATED DIAGNOSTIC TASKS THROUGH PALPATION.** An approach to the design of a robot system capable of executing complex sensory-motor sequences aimed at gathering data useful for diagnostic purposes is presented. The main features of such a robot system are discussed, and its possible integration in an advanced, interactive expert system for medical diagnosis is considered. As an example of implementation of the concept of a robot system for automated diagnostic tasks, the design characteristics of a tendon-actuated, anthropomorphic finger, incorporating force and position sensors for low-level compliant motion control and skin-like sensors for tactile perception, are outlined. The hierarchical control architecture devised for managing some different diagnostic sensory-motor sequences (subroutines) is also presented. The diagnostic subroutine PULSE, which detects pulse rate and optimizes pressure pulse waveform in peripheral blood vessels by noninvasive palpation procedures, is described in detail and then experimentally evaluated in the simplified robot testbed. Preliminary results indicate that the proposed approach may lead to the development of robot systems eventually capable of collaborating with or even substituting for medical or auxiliary personnel in some simple diagnostic and therapeutic tasks. 21 refs.

**090822 AUTOMATIC GRASP PLANNING IN THE PRESENCE OF UNCERTAINTY.** This paper presents an algorithm for automatic planning of robot grasping motions that are insensitive to bounded uncertainties in the object's location. The algorithm plans parallel-jaw grasping motions for arbitrary two-dimensional polygonal objects, which need not be of uniform density. Grasping motions are viewed as parameterized operations, where

the parameter values that describe an individual operation define an operation space of all possible operations. By combining an analysis of object geometry and the physics of friction, the planning algorithm divides the operation space into regions, where all operations within a given region produce the same final grasping configuration. Task uncertainties are then included by shrinking these regions by the amount of uncertainty present. The smaller regions that remain after shrinking indicate all those operations that will successfully result in a given grasping configuration, even if the worst-case combination of errors occurs. The grasping operations presented intrinsically reduce task uncertainty. It is shown that simple squeeze-grasp operations are not sufficient for grasping all possible objects, and offset-grasp and push-grasp operations are added to increase the scope of the planner. (Edited author abstract) 24 refs.

## Reviews

**090827 TENDANCES ACTUELLES ET INTERROGATIONS EN ROBOTIQUE. [Present Trends and Pending Questions in Robotics].** After having defined the various classes of robots: articulated arms, telemanipulators, mobile robots, the article describes summarily the current themes of research: geometric kinematics, kinematics of motion, statics, dynamics, control. A few remarks on the state of research and developments in the United States, in Japan, and at Electricite de France complement the article. (Edited author abstract) In French.

**090828 ROBOTIQUE DE DEUXIEME GENERATION. [Second Generation Robotics].** Robotics, originally starting from mechanical concepts, took advantage of all recent progress in pattern recognition, computation, and computer-assisted design. The second-generation robots will involve the concept of integrated automation including the design of a whole production line, stock management, handling, machining, and even assembling. (Edited author abstract) In French.

**090829 OPTICAL TACTILE SENSOR USING THE CT RECONSTRUCTION METHOD.** The tactile sensors used for robotics and electrical artificial hands are designed to provide force information. This paper proposes a two-dimensional tactile sensor based on the pressure-optical transmission conversion system and the principle of computer tomography. The sensor consists of a three-layered silicon rubber sheet and an array of opto-electrical elements embedded in the edge of the sheet. The pressure distribution is detected as an optical transmission pattern. The transmission pattern is reconstructed to a two-dimensional distribution using the algorithm of the computer tomography (CT) pattern reconstruction. (Edited author abstract) 13 refs.

**090830 CONSISTENT INTEGRATION AND PROPAGATION OF DISPARATE SENSOR OBSERVATIONS.** The author describes a method for integrating partial, uncertain, geometric sensor observations into a robust, consistent estimate of the state of the environment. The integration process uses a Bayes procedure for comparing disparate observations of geometric features, rejecting spurious measurements, and providing partial updates of object locations to a world model. This integration mechanism can combine any number of observations from sensors that provide measurements of different geometric features. The invariant topology of

relations between uncertain geometric features is used to develop a method for propagating observations through the world model. (Edited author abstract) 14 refs.

**090831 ANTHROPOMORPHIC ROBOT FINGER FOR INVESTIGATING ARTIFICIAL TACTILE PERCEPTION.** The design, implementation, and testing of an artificial tactile sensing system incorporating an articulated robot finger are presented. It was our primary aim in this work to set up the hardware and software tools necessary for investigating basic issues in artificial tactile perception. The criteria followed in the design of the robot finger and of its motor and sensory components are outlined. The authors also deal with the problem of defining a hierarchical architecture for the control of the exploratory finger. Experimental results that demonstrate the capability of the robotic system of executing the previously defined tactile subroutines and of extracting specific object features are presented. This work is of interest to prosthetics. (Edited author abstract) 41 refs.

**090832 SATELLITE-MOUNTED ROBOT MANIPULATORS - NEW KINEMATICS AND REACTION MOMENT COMPENSATION.** When a robot arm is mounted on a satellite, the commanded arm motions produce motion of the satellite and therefore of the robot base. As a result, the robot joint angles that would normally be commanded to produce a prescribed robot end-effector position and orientation will cause the end-effector to miss the target. We have developed a new kind of robot kinematics that adjusts the joint angle commands to account for base motion. Methods are also developed to compute the satellite attitude disturbances resulting from robot motion for use in a reaction wheel compensation system or in feedforward control. (Author abstract) 3 refs.

**090833 CONTROL DEVICE EFFECTS ON TELEROBOTIC MANIPULATOR OPERATIONS.** A series of simulation tests were performed to evaluate control input devices for the Remote Manipulator System (RMS). Six subjects operated the simulated RMS in the manual end effector mode using two three-degrees-of-freedom (DOF) hand controllers and one six-DOF hand controller. Two mission scenarios were used to vary operator workload. A task requiring docking to a stationary target from a six-DOF tracking task was used to provide a high-workload condition. Performance using the two types of controllers was compared in terms of task time, measures of position error, and operator ratings of two controller types. (Edited author abstract) 4 refs.

**090834 ROBOTIC SYSTEMS FOR NASA GROUND-BASED RESEARCH.** The laboratory Telerobotic Manipulator (LTM) is being developed at ORNL under the direction of NASA Langley Research Center to provide telerobotic hardware for use in NASA ground-based laboratory research. A significant technical limitation is the lack of available telerobotic hardware that can function well as a real-time teleoperator and can also provide a sound hardware basis for intelligent robotic operations. The LTM is being developed to merge these technical domains in common hardware to further NASA's research investigations. This article summarizes the mechanical and controls approach being utilized to realize these goals. (Author abstract) 4 refs.

**090835 TELEOPERATION AND AUTONOMY FOR SPACE ROBOTS.** A logical enhancement to manned space flight includes the use of robots in space. To achieve this goal, there must be a phased program where the capabilities of the robot can evolve as technology advances. This paper will review some of the ways in which robots can be used in space. Then, a system architecture standard will be suggested which supports the evolution of robot control from teleoperation to autonomy. Finally, some areas of technology transfer will be discussed which are relevant to land-based robot operation. (Author abstract) 5 refs.

**090836 GENERALIZED UNFOLDINGS FOR SHORTEST PATHS.** We consider the problem of determining shortest paths in the presence of polyhedral obstacles between two points in Euclidean three-space. For the special case when paths are constrained to the surfaces of three-dimensional objects, simple planar unfoldings are used to obtain the shortest path. For the general case when paths are not constrained to lie on any surface, we describe generalized unfoldings wherein the shortest path in the three-space again becomes a straight line. These unfoldings consist of multiple rotations about the edges of the polyhedral obstacles. (Author abstract) 11 refs.

**090837 SINGULAR CONFIGURATIONS AND WORKSPACE OF ROBOTS.** The purpose of this paper is to explain the set-up of a general method for finding the singular configurations of a robot. Open and closed chain manipulators made out of links with single degree of freedom joints are considered. The manipulator singular configurations corresponding to inner and outer limits of workspace are found by the study of analytical relations between the end effector location and the joint coordinates using the Jacobian matrix. (Author abstract) 4 refs.

**090838 FUZZINESS IN KNOWLEDGE-BASED ROBOTICS SYSTEMS.** This paper addresses how fuzziness is employed in a robotics system, for the purposes of object representation, object or feature location and as a means of representing actions performed on objects. It describes a robotic system which would use a multimodal representation knowledge base (KB). The focus is on the use of fuzziness in this robotic system. Keyboard entered natural language phrases would be used by a human user of the robot. The robot system would, in practice, translate these phrases into executable commands and coordinates. There are several points of departure that would be employed and the first of these is the use of 'fuzzy descriptors' rather than the conventional binary distinctive feature matrix. A fuzzy descriptor is a generalization of a geometric description of an object from the system's geometric data base. How the fuzzy descriptor works is described. (Edited author abstract) 21 refs.

**090840 MACHINE VISION FOR ROBOTICS AND AUTOMATED INSPECTION.** Volume I of this publication deals with fundamentals in 13 chapters. Some of the topics dealt with are these: the need for vision in industry; cameras, pixels, and lighting; computer approaches to vision understanding; model machine vision systems; general methods to enable robots with vision to acquire, orient, and transport workpieces; and the future of machine vision. Volume II deals with applications in 10 chapters. The topics dealt with are these: automated inspection; alphanumeric character recognition; vision for robots; part handling, orientation, and sorting; assembly; bin picking; semiconductor manufacturing and inspection; printed circuit board inspection; spray painting; and welding. Volume III deals with manufacturers/systems. It consists of product literature with as many details as possible of machine vision systems from manufacturers identified by a multi-faceted effort. The information provided by the manufacturers has not been evaluated, edited, or summarized.

**090841 MACHINE VISION SYSTEM FOR ROBOTIC ASSEMBLY: A SYSTEM OVERVIEW.** The development of a machine vision system is described. The system can acquire an image, identify a desired candidate for the object, and calculate robot goal coordinates. The system consists of a binary vision assembly with both hardware and software subsystems, the hardware consists of a camera, lens controller and lighting. The software consists of a high-level robot control language for multi-tasking and image processing and a menu-driven program for ease of application. The paper presents a concise review of the design goals, system, functions, vision calibration, teach process, application program and capabilities of the assembly. (Author abstract) 5 refs.

**090842 MICROCOMPUTER-BASED BINARY VISION SYSTEM.** This paper describes the development of a microcomputer-based, low-cost binary vision system to be used in automatic applications such as the control of an industrial robot. The vision system processes binary images and recognizes objects based on geometric features such as the number of holes and the moments of invariant. The system is trained by showing it the different stable positions. The image processing software is written in 8088 Assembly code and can recognize up to 40 parts per minute. (Author abstract) 14 refs.

Petersen, V. (Iowa State Univ of Science & Technology, Ames, IA, USA); Even, J. *Int J Appl Eng Educ* v 1 n 6 1985 p 405-413.

**090843 CAD-INTEGRATED VISION AND ROBOTICS.** A data-driven automated SMT board assembly is described that can handle production runs as short as five PCBs per model number. The system relies on integrated CAD information downloaded to an IBM AT master cell controller that is integrated with a dual Xenotech vision system, a Seiko RT3000 robot and a high-speed database management system. All of these run on a multi-user, multi-tasking operating system. The system automatically verifies pad locations, calculates ideal assembly sequencing, determines ideal parts feeding locations, and inspects and adjusts leaded component placement positions to compensate for lead bend variations.

**090845 SOME LOCATION PROBLEMS FOR ROBOT NAVIGATION USING A SINGLE CAMERA.** One of the most fundamental problems for a mobile robot is to find its location and posture with respect to the outside world. The paper considers two classes of point location problems found in visual navigation of a mobile robot. The problems we consider are finding the location of a robot using a map of the room where the robot moves and an image taken by a camera carried by the robot. (Edited author abstract) 13 refs.

Sugihara, Kokichi (Univ of Tokyo, Tokyo, Jpn). *Comput Vision Graphics Image Process* v 42 n 1 Apr 1988 p 112-129.

**090846 DYNAMIC SCENE ANALYSIS FOR A MOBILE ROBOT IN A MAN-MACHINE ENVIRONMENT.** This paper describes a method by which a moving robot with vision can recognize the environment and behave in a proper way by analyzing the consecutive images taken during movement in an artificial environment such as a building or plant. The environment is assumed to be a corridor in a building. Two general features of the corridor are used as the premises for the image analysis: (1) the wall of the corridor is planar and is perpendicular to the floor; (2) the floor is flat. Since it is difficult to determine simultaneously the five three-dimensional motion parameters, a method is proposed to determine successively the parameters by partitioning them into the rotation and translation components. The rotation is determined based on such points in the image as vanishing based on such points in the image as vanishing point and infinity point, which are not affected by determined from the optical flow and the rotation. The position information in the corridor is determined further. The method is versatile since it does not employ the geometrical model represented by numerical values, utilizing only the properties valid in most of the artificial environment. An experiment is made in the corridor of a building. (Edited author abstract) 11 refs.

**090847 ROBOT VISION SYSTEM IMPLEMENTED BY A MINICOMPUTER.** A robot vision system has been introduced. The system consists of an image contour sensor and a minicomputer model PDP-11/23. The image contour sensor contains an image-dissector-camera. The processing of the image information has been carried out by this computer so as to

recognize and understand the image contour. The relevant information for image analysis and classification is contained in image contours. The image-dissector-camera is suitable for the randomly-controlled scanning of optical signal. Controlled by a minicomputer, the scanning generator can produce a 'scanning star' for contour detection. The automatic contour tracking is carried out by Kalman-Bucy-filter algorithm. Thus the data processed by the computer are reduced. It can realize a syntactic graph structure based on the structure element of 'node-relation-node' as well as an associative syntactic pattern recognition. (Edited author abstract) 3 refs. In Chinese.

**090848 DESIGNER'S HANDBOOK: SPATIAL RESOLUTION. A KEY TO MACHINE VISION SUCCESS.** When integrating machine vision capabilities into any system, a number of factors need to be considered. The author will define and clarify these factors, discuss their interaction and provide a systematic approach to determining spatial resolution requirements and selecting a system with the most appropriate spatial resolution. The article will focus on alignment applications; the methodology for determining resolution in flaw detection or inspection applications is somewhat different, and will not be addressed.

**090849 HITCHHIKER'S GUIDE TO VISION SYSTEMS.** This article offers criteria for choosing a vision system. Three tasks were defined as representative of generic areas of application. These were biscuit inspection which has always been a favorite of vision suppliers (or perhaps just the engineers who work for them); date and lot code inspection on pharmaceutical or food products and dimensional checks on a cassette tape assembly. In addition to technological constraints the author also imposed financial limits on the application of the system.

Loughlin, Clive. *Sens Rev* v 8 n 2 Apr 1988 p 93-99.

**090850 LOOK FORWARD TO NON-CONTACT TASKS.** This article traces the latest developments in machine vision systems. The reasons why engineers should keep abreast of the technology's potential for non-contact inspection tasks, for example, are highlighted.

Astrop, Arthur. *Mach Prod Eng* v 146 n 3738 May 6 1988 p 56-57.

**090851 EYES OF THE FACTORY - ROBOTS WITH VISION.** Vision systems applications include handling discrete materials (traveling on a conveyor, or stored in a bin) for the purpose of sorting, packaging, palletizing, or machine feeding, guiding materials through such processes as finishing, deburring, cutting, and sealing, and directing the fitting and fastening motions required for assembly. Vision works best when applied to stable products in a well controlled environment. The benefits of such systems include: increased productivity; increased throughput; better manufacturing control; increased robotic cell flexibility; and decreased sophistication in presenting materials to robots.

Krepchin, Ira P. *Mod Mater Handl* v 43 n 6 May 1988 p 89-91.

**090852 OPTIMIZING INSPECTION LOCATION.** Automated inspection systems provide a powerful tool for quality control as well as process control in a wide variety of industries. Such systems pay for themselves in a short time by providing real-time information - identifying problems on the production line as they occur - thus minimizing the manufacture of 'off-spec' product. Data from a computerized inspection system can be used for trend analysis, quality assurance, and production management. Optimizing the benefits of automated inspection now is possible with new technology that allows manufacturers to inspect at both the serial and parallel stages of

the production line. Both stages offer paybacks which can work together to bring well-defined savings. Author describes the advantages of optimizing inspection location and its effect on statistical process control.

Sawyer, William H. (Computer Based Imaging Technologies, Malvern, PA, USA). *Rob World* v 6 n 3 Mar 1988 p 20-23.

**090853 LIGHTING AND OPTICS: SOME EXPERT ADVICE.** The Lighting Advisor expert system, developed by Penn Video, was created to help solve lighting and optics problems mainly for small parts assembly verification. The Lighting Advisor uses a personal computer as its work station. The software is menu-driven with help available at all times. The user tells the Lighting Advisor about the application by answering a series of questions and making choices from the menus. The questions pertain to the nature of the application, the feature and background surface qualities, whether the object is moving or stationary during the inspection, etc. The expert system reviews the answers given and returns a set of conclusions, including: the lighting technique; the light source; the camera lens; and possible color or polarized filtration or special optics requirements.

Novini, Amir (Penn Video, Akron, OH, USA). *Rob World* v 6 n 6 Aug 1988 p 34-35.

**090854 PRECISION HIGH-SPEED RANGE SENSOR AND PROCESSOR.** A 3-D camera that measures 180,000 points per second with 25 microns range accuracy has been developed. This camera is applied to inspection of electronic assemblies, especially printed wire boards (PWB). A second important application is the more traditional problem of measurement and inspection of mechanical parts and assemblies with significant three-dimensionality. This paper provides range camera description, discusses vision computer and workstation and describes two examples of camera application: lead through hole (LTH) inspection in PWB and top of board inspection.

Corby, N.R. Jr. (GE, Schenectady, NY, USA). *Sens Rev* v 8 n 3 Jul 1988 p 155-160.

**090855 AUTONOMOUS NAVIGATION, EXPLO- RATION, AND RECOGNITION USING THE HER- MIES-IIB ROBOT.** The authors describe a research experiment in which an autonomous robot, the HER- MIES-IIB, placed in an arbitrary indoor location without prior specification of the room's contents, successfully discovers and navigates among both stationary and occasionally moving obstacles, picks up and moves small obstacles, searches for and locates a control panel, and reads meters found on that panel. All computation is done onboard the robot, which contains an eight-node NCUBE parallel processor. Available sensors include an array of sonar transducers and two cameras. The robot uses an expert system for real-time navigation, implementing machine vision algorithms that run in parallel on the nodes for panel recognition and meter reading. The authors discuss dynamic replanning, rapid decision-making under uncertainty, and computational capability within the context of an indoor laboratory environment. 19 refs.

Burks, Barry L. (Oak Ridge Natl Lab, TN, USA); de Saussure, Gerard; Weisbin, Charles R.; Jones, Judson P.; Hamel, William R. *IEEE Expert* v 2 n 4 Winter 1988 p 18-23, 26-27.

**090856 DETERMINING OBJECT MOTION IN A SEQUENCE OF STEREO IMAGES.** The motion of a three-dimensional object is determined from a sequence of stereo images by extracting three-dimensional features, establishing correspondences between these features, and computing the rigid-motion parameters. Three-dimensional features are extracted from the depth map of a scene. A two-pass relaxation method is developed for matching features extracted from successive depth maps. In each iteration, geometrical relationships between a

feature and its neighbor in one map are compared to those between a candidate in the other map and its neighbors to update the matching probability of the candidate. The comparison of the geometrical relationship is based on the principle of conservation of distance and angle between features during rigid motion. The use of three-dimensional features allows the rotation and translation components of motion to be found separately by via solving linear equations. Experimental results using several sets of real data are presented. 34 refs.

Kim, Yeon C. (Univ of Texas, Austin, TX, USA); Aggarwal, J.K. *IEEE J Rob Autom* v RA-3 n 6 Dec 1987 p 599-614.

**090857 ROBOT VISION TRACKING SYSTEM.** A system designed to test a tracking theory for finding the position of an object in a scene, even when it is entering or exiting, is described. The design of a servo system used to move the camera while tracking the object is proposed. The technique involves the fundamental frequency of the Fourier transform of the vertical and horizontal projections of the image. This technique will work with stationary or moving objects as well as with a stationary or moving camera. The objective is to apply this technique to find the line between the camera and the object, such that the robot arm could follow that line until it encountered the object, and then seize it. This technique may also be useful in performing camera calibration. 10 refs.

**090858 VISION AND NAVIGATION FOR THE CARNEGIE-MELLON NAVLAB.** A distributed architecture articulated around the CODGER (communication database with geometric reasoning) knowledge database is described for a mobile robot system that includes both perception and navigation tools. Results are described for vision and navigation tests using a mobile testbed that integrates perception and navigation capabilities that are based on two types of vision algorithms: color vision for road following, and 3-D vision for obstacle detection and avoidance. The perception modules are integrated into a system that allows the vehicle to drive continuously in an actual outdoor environment. The resulting system is able to navigate continuously on roads while avoiding obstacles. 15 refs.

**090861 WHERE ARE THE ROBOTS?** Japan has more robots than any other country in the world; even Europe is ahead of the United States. Robot technology has the potential to be the most human-felt ingredient of the computer age. Why is it, then, that U.S. industry is lagging in installing robots? The answer put forth by the author is that the Japanese are totally committed to manufacturing. Also, they have pursued a national goal of quality in manufactured goods for the past 30 years - the same period during which the United States was losing interest in manufacturing.

Reeve, Ronald C. Jr. *CHEMTECH* v 17 n 2 Feb 1987 p 72-75.

**090862 GEOMETRIC TOOLS FOR THE OFF-LINE PROGRAMMING OF ROBOTS.** Off-line programming of robots has a number of clear advantages over traditional 'teach' methods which require the robot to be taken out of production. However, off-line programming techniques require extensive geometric facilities which are ideally provided by a geometric modeling system. The use of modeling covers the planning of the robot workcell, as well as the detailed planning of the robot operations. Assembly, in particular, requires detailed geometric information concerning geometric features and solid properties. (Author abstract) 9 refs.

**090865 PLAN GENERATION IN ROBOTICS.** We present the state of the art of automatic plan generation,

with emphasis on its application to robotics, as well as some personal perspectives on the topics covered. We begin presenting a panoramic view of the first attempts at plan generation, but as yet, not connected with robotics. A survey was made of the main problems to be met when it is intended to plan for a real executor in a real world. Next, the case of distributed robotic systems and its implications on plan generation is examined. The question of time and its explicit representation is also looked upon. A view of learning and specialized plan generators is given. (Author abstract) 74 refs.

**090866 DYNAMIKUNTERSUCHUNGEN VON INDUSTRIEROBOTERN MIT DEM PROGRAMMPAKET CAE-IR.** [Studies of Dynamics of Industrial Robots by Means of the Program Packet of CAE-IR]. The program CAE-IR is a result of research cooperation of institutes and universities in Leningrad, Irkutsk and Riga as well as in Berlin and Mittweida within the governmental agreement between USSR and GDR. It allows modeling basic units for robots as variable and simulation of their dynamic performance. Its performance is demonstrated in an example of the positioning control system of the paint spray robot IFA-TR 10. (Edited author abstract) In German. 9 refs.

**090867 THEORY OF KINEMATIC PARAMETER IDENTIFICATION FOR INDUSTRIAL ROBOTS.** This paper presents the concept of completeness for kinematic identification of robot manipulators. Completeness is defined as the ability to map joint positions into tool positions for all arbitrary manipulators. It is suggested that complete models must contain a certain number of independent parameters. Furthermore it is suggested (and shown by practical examples) that the required number of independent kinematic parameters is easy to determine a-priori. This enables one to check a model for completeness. Although the basic idea behind kinematic identification may have been considered well known, several identification algorithms in the recent literature are incomplete. Two examples are included in this paper. For this reason, this paper presents the topic and includes the conditions for a complete and viable identification algorithm. (Author abstract) 19 refs.

**090868 WORKSPACE ANALYSIS OF 4R MANIPULATORS WITH VARIOUS DEGREES OF DEXTERITY.** For 4R manipulators and their various configurations, workspaces with full, partial, and zero dexterity are defined, and a procedure to determine them is developed. As examples, two 4R manipulators are analyzed. Subspaces with 2, 4, 6, and 8 configurations and various degrees of dexterity are found. Several points on the effect of geometrical parameters on the shape and extent of the boundary surfaces, subspaces, and number of configurations are discussed. An index for the evaluation of the degree of accessibility of the workspace of a manipulator is also proposed. (Author abstract) 23 refs.

**090871. ROBOTICS MACHINING SECTION BASED ON TWO PUMA-560 FA ROBOTS.** For processing of components of the body-of-revolution type the 'Elektrosila' Leningrad-Pskov Electric Equipment Combine has developed, fabricated, and introduced the 'Val-2' ('Shaft-2') robotics section (IS), based on two Puma 560-FA electromechanical robots produced by the Nokia Company, Finland. The section is intended for cutting of ends and centering of workpieces, lathework, trimming of ends, application of measurement markers, knurling, and packing of parts in containers.

**090872 ON THE ELIMINATION OF BRANCHING IN THE SYNTHESIS OF SPATIAL SINGLE-LOOP MECHANISMS WITH LOWER PAIRS.** A single-loop spatial mechanism kinematically becomes an open robot, if we separate the grounded joint of the input link which may then be considered as the end effector of the robot. Any position of the end-effector within the workspace of such an open robot can be reached via a number of different configurations of the links. These configurations are called 'branches' of the open robot for that particular position of the end effector. If the open robot is now stretched to a limiting position by a force exerted on the end effector, all the possible branches of the mechanism approach each other. When they become coincident, they form the 'limiting configuration'. Any two related branches are at opposite sides of the limiting configuration. From the relationship between the links in the limiting configuration and in related branches, conditions for avoidance of branching of the original closed-loop mechanism can be obtained. (Edited author abstract) 13 refs.

**090875 PROCEEDINGS OF '85 INTERNATIONAL CONFERENCE ON ADVANCED ROBOTICS.** The proceedings contains 72 papers. The papers are grouped under the following session headings: trends in robotic research; intelligence; sensory systems; manipulation; teleoperation; application in nuclear plant; locomotion; integrated system' large-scale national R&D project 'advanced robot technology'; and overviews on advanced robotics. Some of the specific topics discussed are: collision avoidance; a robot slide sense control system; computing of robot's workspace; a computer aided manipulation system for multijoint inspection robot; kinematics of six-legged vehicle on irregular terrain; speech conversion system of the musician robot; and the mechanics of mobile robots. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11307 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

## Accidents

**090877 HAZARD IDENTIFICATION AND SAFETY ASSESSMENT OF HUMAN-ROBOT SYSTEMS.** The purpose of this paper is to develop a systematic methodology for safety improvements of human-robot systems at present and for the future. Various types of robots are briefly summarized together with safety aspects specific to robots. Historical reviews are given of typical industrial incidents caused by robots. The paper outlines safety assessment procedures which are consistent with the probabilistic risk assessment procedures typically used for systems in the nuclear, chemical, and aerospace industries. Character analyses and hazard causation mechanisms are analyzed for a general human-machine system. The authors consider the human-robot system, and enumerates possible hazards. 7 refs.

Kumamoto, Hiromitsu (Kyoto Univ, Kyoto, Jpn); Sato, Yoshinobu; Inoue, Koichi. *Eng Risk and Hazard Assessment* v 1 p 61-80.

**090878 SAFETY OF CNC AND ROBOT TECHNOLOGY.** The incidence of robot and CNC related accidents has not been considered a significant occupational safety issue. It is suggested that this is partly due to a process of denial arising from the belief that accidents involving such machines cannot occur except in cases of gross negligence. It is argued that control processes founded on advances in information technology redistribute the risk of injury rather than eliminate that risk. This is likely to lead to the replacement of 'traditional' accidents, about which we know quite a lot, with information technology accidents, about which we know relatively little. (Author abstract). 23 Refs.

## Analysis

**090879 ROBOT-MOTION PATH-PLANNING ALGORITHM WITH DYNAMIC PROPERTIES OF ACTUATOR MODELS.** A general planning algorithm for robot paths based on the intrinsic motions of a dynamic model of the final unit that pass it through the initial and target positions is validated and described. The boundary-value problem is solved by differentiation with respect to a parameter, and the values for the parameters of the final-unit dynamic model. (Author abstract) 10 refs.

Tyves, L.I.; Markevich, S.V. *Sov Mach Sci* n 4 1987 p 23-29.

**090880 CLOSED-LOOP DYNAMICS ANALYSIS BY APPEL'S METHOD.** Dynamics analysis of industrial robots with a constrained (closed-loop) dynamic system is often needed under operating conditions such as insertion, deburring, etc. The authors have been developing dynamic simulation programs for an open-loop dynamic system with arbitrary construction of robots. Appel's method is used for the description of the equation of motion in these programs. Since industrial robots are often used under various constraint conditions, it is preferable to simulate robot motions under various operating conditions if the direction and degree of freedom of the constraint can be selected arbitrarily in the programs. In this respect, this paper first refers to an analytical method of closed-loop dynamics by Appel's method using Lagrange multipliers, which can be easily extended from analysis of open-loop dynamics to that of closed-loop dynamics. Then numerical analysis of the robot motion under constrained condition is carried out and the validity of this method is shown. (Author abstract). 9 Refs.

## Anthropomorphic

**090881 ROBOT MUSICIAN 'WABOT-2' (WASEDA ROBOT-2).** The WABOT-2 is an anthropomorphic robot playing keyboard instruments, developed at Waseda University. The WABOT-2 is equipped with hands tapping softly on keys, with legs handling bass keys and expression pedal, with eyes reading a score, and with a mouth and ears to converse with humans. Based on Wabot-2, WASUBOT has been developed by Sumitomo Electric Industries Ltd. Its artistic skill has been demonstrated in performing music at the Japanese Government Pavilion in Expo '85. The paper summarizes the WABOT-2's motion, visual and vocal subsystems as well as its supervisory system and singing voice-tracking subsystem. (Edited author abstract)

**090883 STUDY OF THE RANGE OF MOTION OF HUMAN FINGERS WITH APPLICATION TO ANTHROPOMORPHIC DESIGNS.** The multifingered human hand serves as a model for anthropomorphic manipulators and prosthetic devices. In order to better guide the design of these devices, a study of the range of motion of human fingers is presented. The role of tendons in the actions of human fingers is modeled and results of experimental studies on the range of motion of fingers in normal humans are presented. Further study of disabled hands illustrates constraints imposed by deficient tendon mechanisms. The basic investigations of normal and disabled hands guide the design of tendon-based actuators for mechanized fingers. The design of a prototype finger actuated by a shape-memory alloy material serving as a tendon is discussed. 18 refs.

**090884 ROBOT COMPLEX FOR MECHANICAL TREATMENT OF EXCAVATOR PARTS.** One of the main trends in automation and mechanization of production is the creation of robot complexes (RC) based on industrial robots (IR). RC for mechanical treatment represent a processing system based on one or several metal cutting stands served by one or several IR. The authors consider the organization of a robot complex using as example the creation of RC for manufacturing fastening parts for EKG-8, EKG-10, and EKG-12 excavators. According to the existing processing scheme a bar forging with a head serves as blank. Blank transport into the treatment zone, clamping in the cartridge, startup of the stand, transport of the part to the finished production container are all carried out manually.

gos); Vujic, D. *Mech Mach Theory* v 22 n 5 1987 p 421-429.

**090886 ASSEMBLY WITH ROBOTS.** The general and specific implications of performing an assembly task robotically are discussed, the majority of which are not specific to any one sector of the manufacturing industry, nor to any particular size of product being manufactured. First, the purpose of the use of robots is discussed, their availability, purchase and viability, and the robot market is assessed. The choice of robot configuration, capability, programming method, specifications, methods for calculating the cycle time, and assessing workload are discussed. Descriptions of grippers, assembly techniques, product compatibility and process design for assembly, workstations, material feeders, sensing and vision are presented. Problems of the interaction between man and machine, safety procedures and devices are discussed. Methods of evaluation of a robot system, economics of alternative systems; economics of robots and grippers, and the outlook for the future is considered. An appendix lists the assembly robots available in the USA and the UK. 27 refs.

**090887 ROBOTICS COMPLEX FOR STAMPING OF CABLE TERMINALS.** The robotics complex (RC) consists of the following: the model MP-98 robot, the cycle control system (type ETsPU-6030), eccentric press, two-position die, a device for piece-by-piece loading of blanks into the die, the lubrication mechanism, the device for removing terminals to the container, and the enclosure. The complex provides for fabrication of cable terminals in six sizes with minimum readjustment from one size to another.

Ginzburg, Yu.M. *Sov Electr Eng* v 57 n 7 1986 p 108-109.

**090888 PRAKTISCHER EINSATZ SENSOR-GEFUEHRTER SCHWEISSROBOTS.** [Application of Sensor-Guided Welding Robots]. Automation of manufacturing processes by means of industrial robots has been gaining in importance because this technology permits higher productivity at increased flexibility. Substantial growth rates are recorded in particular for industrial robots for spot and seam welding. In spite of this situation, the latest Frost & Sullivan study about the state of welding technology in Europe witnesses that welding by means of industrial robots is handicapped by a lack of appropriate sensors. In the 1986 annual survey of welding and flame cutting, the essential weaknesses of sensor use are quoted to be lack of availability, excessive investment costs, frequently insufficient flexibility and lack of interface standardization. These statements were confirmed by own experience in the application of welding sensors in the German automotive industry. This report is intended as a study of the requirements to be considered as representative for users, of the range of sensor principles available in industrial configuration, and of how the problems handicapping sensor use should be solved from the viewpoint of users. (Edited author abstract) 10 refs. In German.

Rogos, J. *Werkstatt Betr* v 120 n 9 Sep 1987 p 727-732.

**090889 INDUSTRIEROBOTER UND SICHERHEIT BERICHT VON DER VDI-FACHTAGUNG AM 12. MAERZ 1987, BAD SODEN/TS.** [Industrial Robots and Safety Report on the VDI Conference at Bad Soden on March 12, 1987]. 'Safety first' was the central motto of a forum held by Verein Deutscher Ingenieure (VDI). Within the overall complex of 'industrial robots in safety concepts for automatic manufacturing facilities', representatives of big and small users gave their views about reasonable procedures for planning facilities with industrial robots. Reports from practical application and transfer of experience were in the foreground for conceiving this forum which was primarily intended for managers and experts from the sector of planning, production, safety and maintenance. Implementation of existing accident prevention requirements and the results of the VDI committee on working safety of assembly and handling equipment were the central points of the subjects dis-

cussed. (Author abstract) In German.

**090900 SENSORGESTUETZTE PROGRAMMIERUNG UND STEUERUNG VON INDUSTRIEROBOTERN.** [Sensor Based Shape Scanning and Trajectory Planning by Industrial Robots]. An important application of sensor-equipped IR is the automatic scanning of a priori unknown contours and shapes of workpieces. During the sensor-based scanning different manufacturing operations requiring moderate path velocities (< 100 mm/s) can be performed simultaneously. Typical applications are deburring or seam welding. In this paper a modularly structured system of algorithms both for sensor based contour tracking and automatic generation of fast and accurate reference trajectories (IR programs) will be introduced. Practical experiences concerning the coupling of optical and tactile sensors with an IR-control hardware are reported on. (Edited author abstract) 16 refs. In German.

**090901 ROBOTS ANSWER CHALLENGE AT NORTHERN TELECOM FACTORY.** Offshore competition left the management of the Northern Telecom plant in London, Ontario, with two alternatives: reduce product cost substantially or relocate the plant to an area with

lower labor costs. Management and labor agreed to develop a new telephone product, designed for automated manufacturing. The design changes were dramatic. The old product had 380 components (mostly mechanical), 44 fasteners, and 24 free leads. The new telephone uses 120 components (mostly electronic), seven fasteners, and only two free leads. Using existing resources and facilities, Northern initially made its 'new' phone by hand to meet introduction schedules. Automation for circuit board assembly was limited to stand-alone equipment such as radial and axial insertion machines by Universal Instruments Corp., Binghamton, N.Y. These islands of automation provided the initial step for Northern's automation efforts. Seeking product flexibility, Northern Telecom decided to integrate existing equipment in its circuit board population department with robotics for odd-form component insertion and machine loading.

**090903 ROBOTIQUE ET DEMANTELEMENT.** [Robotics and Dismantlement]. The dismantling of nuclear power plants which are not in use is going to develop in the coming years and will have to use the latest technologies in robotics. In particular, C.A.T. technologies will be indispensable to solve the safety and productivity problems which will arise. (Edited author abstract) In French.

Parent, Michel (CYBERG, Fr). *Rev Energ* v 38 n 395 Sep 1987 p 439-440.

**090904 3-D SYSTEM LOCATES CARS FOR ROBOTIC SEALING.** Inaccuracies cannot be tolerated in automobile seam sealing because of the expensive material used. Author describes a 3-D vision system that locates the car position and adjusts the robot's path to that position.

Baker, Paul D. (Robotic Vision Systems Inc, Hauppauge, NY, USA). *Rob World* v 6 n 3 Mar 1988 p 28-29.

**090905 THREE-ROBOT WORKCELL INSTALLS CONTACTS INTO PLASTIC BLOCKS.** Author describes a robotic workcell designed and developed by Vanguard Automation Inc. which installs contacts into plastic connector blocks using 3 Seiko robots working in conjunction with a rotary index table. The system is capable of installing contacts into five different styles of connectors varying from 28 to 82 contacts per connector.

Anon. *Rob World* v 6 n 3 Mar 1988 p 34.

**090906 GLUE DISPENSING STATIONS REDUCE LABOR NEEDS BY HALF.** Author describes a robotic system which automatically applies water deflectors to car door panels. The benefits of this robotic system are the material savings and increased productivity.

Anon. *Rob World* v 6 n 3 Mar 1988 p 37.

**090907 ROBOTS IN THE SHEARING SHED: AUTOMATED SHEARING OF SHEEP USING ROBOTS.** The Australian wool industry has sponsored a long-term program to find alternative ways of harvesting wool from sheep. Research into automated shearing started in 1975 and by 1977 automatic shearing of wool from sheep had been demonstrated. In that year, the University of Western Australia commenced a research program which has led to the development of specialized

sheep-shearing robots. Practically all of the technical problems have been successfully solved and present research work is directed towards small-scale demonstrations of automated shearing to promote acceptance of the idea. The Australian Wool Corporation, which is responsible for administering the research funding, has not yet decided to proceed with commercial development. (Edited author abstract).

**090908 DEVILBISS UNVEILS NEW ROBOTIC MACHINE FOR CAR INDUSTRY.** New high standards of quality paint finishing of motor cars are being achieved by an automatic system currently being unveiled by the DeVilbiss company to potential customers from all over Europe and America as well as the UK. DeVilbiss E, as the robotic machine is called, is a long stroke, four-axis unit designed specifically for car body external surface top and side coating - a market deliberately avoided by DeVilbiss to date. This article presents a design overview of the robotic machine.

**090910 ROBOT MOTION AND TASK PLANNING: SIMULATION AND PROGRAMMING OF A ROBOT ARM.** A robot simulation system has been developed to assist in robot task planning and control data programming. The system allows simulation of the robot manipulator on the CRT by taking into consideration the kinematics and dynamics of the robot arm. The architecture of the robot simulation system is presented. Description of robot positional kinematics is given by the use of geometrical model and its extension to homogeneous transformation. Several simulated robot arm positions are shown to illustrate the kinematic model. (Author abstract) 23 refs.

**090911 MODELING AND CONTROL CHARACTERISTICS FOR A TWO-DEGREES-OF-FREEDOM COUPLING SYSTEM OF FLEXIBLE ROBOTIC ARMS.** The dynamic characteristics of flexible robotic arms with two-degrees-of-freedom are modeled with consideration of the coupling between the first and the second arms under the assumption that each arm vibrates only due to the bending moments. In order to suppress vibration in positioning control such basic characteristics of the flexible robotic arms must be employed for the decoupling control. A decoupling control method is proposed by the feedback control method to compensate for the coupling effects between the flexible robotic arms. Experiments are then demonstrated to show the effective-

ness of the proposed method. Finally, a method of collision control is also shown as one of applications. (Author abstract) 10 refs.

**090913 DYNAMIC PATH PLANNING FOR A PLANAR ARTICULATED ROBOT ARM MOVING AMIDST UNKNOWN OBSTACLES.** This work is concerned with planning collision-free paths for a robot arm moving in an environment filled with unknown obstacles, where any point of the robot body is subject to collision. To compensate for the uncertainty, the system is provided with sensory feedback information about its immediate surroundings. In such a setting, which presents significant practical and theoretical interest, human intuition is of little help, and designing algorithms with proven convergence thus becomes important. We show that, given the target position, local feedback information is sufficient to guarantee reaching a global objective (the target position) and present a nonheuristic algorithm which generates reasonable collision-free paths. In this approach, the path is being planned continuously (dynamically), based on the arm's current position and on the sensory feedback. A case of a planar arm with two revolute joints is studied. No constraints on the shape of the robot links or the obstacles are imposed. The general idea is to reduce the problem of motion planning to an analysis of simple closed curves on the surface of an appropriate two-dimensional manifold. (Edited author abstract) 28 refs.

**090914 NUMERICAL SOLUTION OF ROBOT ARM INVERSE KINEMATICS AND DYNAMICS.** A new method of a numerical solution of robot arm inverse kinematics and dynamics for a desired trajectory expressed in the task coordinates is proposed. In this method, a desired acceleration expressed in the task coordinates is obtained by differentiating a given desired trajectory of the top of hand with respect to time. Then the desired acceleration is transformed into the acceleration of each joint using kinematic relations. Numerical solution of the inverse kinematics can be realized by numerical integration of each joint acceleration. The method is verified by a numerical example. The advantages of the method are: (1) Inverse kinematics can be solved for any construction of robot having six degrees of freedom. (2) Not only inverse kinematics but also each joint acceleration forces can be obtained. (Author abstract) 10 refs.

**090915 CONTROL OF A FLEXIBLE ROBOT ARM: EXPERIMENTAL AND THEORETICAL RESULTS.** The operation of high precision robots is severely limited by their manipulator dynamic deflection, which persists for a period of time after a move is completed. These unwanted vibrations deteriorate the end effector positional accuracy and reduce significantly the robot arm production rate. A 'rigid and flexible motion controller' is derived to introduce additional damping into the flexible motion. The important issue of control and observation spillover is examined and found to present no significant practical problems. Partial evaluation of this approach is

performed experimentally by testing two controllers, a 'rigid body controller' and a 'rigid and flexible motion controller', on a single joint of a spherical coordinate, laboratory robot arm. The experimental results show a significant reduction in the end effector dynamic deflection; thus partially validating the results of the digital simulation studies. **090917 DECENTRALIZED CONTROL OF NON-LINEAR ROBOT MANIPULATORS.** Robot manipulators have highly nonlinear dynamics. Therefore the control of multi-link robot arms is a challenging and difficult problem. A nonlinear dynamic model is for an n-axis robot arm and a linearized model is obtained for it. The linearized model is considered as an n-controller large-scale system. The notion of decentralized stabilization has been introduced and applied to the robot arm. Controllers considered are PD, PID and PD plus a feedforward (inverse dynamics). Numerical simulation for decentralized control of a 3-axis PUMA arm are included. (Edited author abstract) 8 refs.

**090921 NEW METHOD FOR PATH PLANNING THE MOTION OF ROBOT ARMS.** A new method for path planning the motion of robot arms is here presented. The desired end effector motion along a prescribed path is found together with the corresponding laws governing the displacement in the joints. This method generalizes the existing methods for planning the robot arm motion subject to a preplanned linear and angular displacement of the end effector. Besides, the motions of both non-redundant and redundant robot arms are uniformly treated by the proposed method, while the constraints of the joint variables and the joint rates are simultaneously and explicitly considered. The results obtained by the implementation of this technique in path planning the motion of industrial robots show that it can be successfully applied in achieving the specific quality characteristics needed in a manipulation task performance. 6 refs.

**090922 OPTIMAL CONTROL OF ELASTIC STRUCTURE SYSTEMS TAKING ACCOUNT OF SPILLOVER (APPLICATION TO A POSITION CONTROL OF ELASTIC ROTATING ARM).** A digital controller for an elastic structure system suffers from spillover of residual modes. In this study, this problem is formulated as a control structure constraint for the elastic system. A sub-optimization technique is applied to the optimal control problem with a control structure constraint and a suboptimal control law is derived taking account of the spillover. This method is very simple, since it needs only a solution of the Riccati equation and matrix operations. This method is applied to the optimal positioning control of a rotating elastic arm. In the numerical calculation, it is indicated that the controller system synthesized by this method remains stable and has good control performance, while the one synthesized by the optimal control theory within the reduced order system becomes unstable. Furthermore, the usefulness of this method is demonstrated in the simulation and control experiment. (Author abstract) In Japanese. 12 refs.

**090924 CLOSED-LOOP DISPLACEMENT CONTROL OF A ONE-LINK FLEXIBLE ARM WITH A TIP MASS.** A theoretical and experimental study is presented for the displacement control of a one-link flexible arm with an end-point payload. The tip displacement of the arm is sensed by the gap-sensor fixed in space

and controlled by a D.C. motor located at the other end of the arm, where the motor is driven by a feedback signal composed of the tip displacement and velocity. As an example, the problem of shifting the end-point of the arm from its initial position to the desired position by the amount of  $w_d^*$  is considered. Theoretical results are obtained by applying the method of the Laplace transform to the governing equation, and the solution is obtained by the method of numerical Laplace inversion. Experimental results are obtained and compared with the theoretical ones, from which it is shown that both results are in good agreement for a wide range of parameters. (Author abstract) In Japanese. 8 refs.

**090927 FUNDAMENTAL RESEARCH ON JOINT CONFIGURATION OF INDUSTRIAL ROBOT.** The main parameters for designing kinematic mechanisms of a robot are degrees of freedom, types of joints, length of links and the presence of offset. Although the length of links and offset can be expressed as quantitative evaluation functions, the combination and sequence of the joint types cannot be quantitatively evaluated. The purpose of this paper is to tabulate the arm and wrist joint configuration of a robot with six degrees of freedom. The authors establish rules to exclude duplicate or ineffective combinations of the joint configurations. The results are utilized to design the kinematic geometry of a robot manipulator. **090928 ADMISSIBLE TRAJECTORY DETERMINATION FOR TWO COOPERATING ROBOT ARMS.** The problem of finding an allowable object trajectory for a cooperating two-robot system is investigated. The purpose is to move an object from one point to another by firmly grasping it at two different points using two robotic hands. The major difficulty is caused by the fact that, unless the robots have true six degrees of freedom, the trajectories the object can follow are severely limited and, in general, are difficult to find. The method proposed in the paper is based on reformulating the problem as a nonlinear optimization problem with equality constraints in terms of the joint variables. The optimization problem is then solved numerically on a

computer. The solution automatically gives the corresponding joint variable trajectories as well, thus eliminating the need for solving the inverse kinematic problem. The method has been successfully applied to a real experimental system. (Author abstract) 10 refs.

**090929 OPTIMAL CONTROL OF A FLEXIBLE ROBOT ARM.** This work is a computer simulation of the control of a flexible robot arm. The dynamic equations for a single-link flexible robot arm have been derived rigorously. This arm has two degrees of freedom in rotation and one in translation so that the workspace is three-dimensional. The payload is simulated by attaching additional mass to the arm at a specified location. The governing equations of the plant and the measurements are nonlinear. The process of control is divided into two stages: coarse control and fine control. Based on the optimal control theory, a linear observer is constructed for fine control. The numerical results are presented here. (Author abstract). 11 Refs.

**090931 DEVELOPMENT OF A SIX-DEGREE-OF-FREEDOM VIBRATORY DEVICE FOR LOCATING OBJECTS.** This paper describes a sensor for determining the location of rigid objects. The device can be mounted on the end of a robot arm to enable it to sense the position and orientation of an object it has picked up from a stack or tray. Since the initial location of the object only has to be approximately known, say to  $\pm 25\text{mm}$  and  $\pm 45^\circ$ , this 'stack-picking' (or 'tray-picking') technique has the advantage of not requiring a rigidly ordered environment. Also, because it still makes use of a certain amount of structure in the environment, it is less demanding on the sensing system than vision-based 'bin-picking' systems and therefore is less costly and more practical, in the short term at least. The device consists of an elastic column built-in at one end to the wrist of the robot and a small rigid platform fixed at the other end of the column. The object whose exact position and orientation are to be determined is held on the platform. Static deflections and frequencies of the natural six-degree-of-freedom vibrations of the system are used, respectively, to determine the position of the centre of mass and orientation of the principal axes of inertia of the part. (Edited author abstract). 9 Refs.

**090932 PATH CONTROL OF A ROBOT ARM USING THE LINEARIZED CONSTRAINT CONTROL METHOD.** In present manufacturing systems path control of robots is performed by the teaching/playback method. But this method is not feasible once the job specification of the robot is altered, since the control is based on repeated trial and error to make the motion satisfy a specific performance. For this problem, there are many approaches to establish the off-line teaching method. In this paper the authors propose path control of robots based on linearized constraint control, which has been brought up by the authors in the past. A simulation

confirms that the method produces a good performance and that it can be regarded directly applicable to production robot systems in today's industry. (Author abstract). 15 Refs.

**090933 DYNAMIC CONTROL OF A FLEXIBLE ROBOT ARM BY USING EXPERIMENTAL MODAL ANALYSIS.** A new control method for a flexible robot arm has been developed. First, two methods for piecewise linearized representation of the input-output relation between a control command and the resulting end effector motion have been proposed such that they include the effect of arm flexibility through the use of measured transfer function data of the input-output relation. These methods are then used for predicting a vibratory motion of the end effector which is commanded by a trapezoidal velocity pattern to obtain a good correspondence with the actual motion. Finally, based on the results obtained above, a method to compute the control command which realizes a desired smooth motion has been developed as the inverse method of the above motion prediction. Experimental results show considerable suppression of flexibility-induced vibration of the robot arm. (Author abstract). 5 Refs. In Japanese.

**090934 CONTROL OF MOTION OF A MANIPULATOR ALONG A CONSTRAINT.** Use of force-moment adaptation systems has expanded the capabilities of manipulation robots. This paper considers the problem of maintaining contact with a fixed object (solved on the basis of force information) as the robot grip moves along the contour of the object (i.e., along a constraint). This type of motion may be employed to determine the contour of objects, to follow a weld in automatic welding, or for abrasive cleaning or grinding. The experimental studies employed a two-handed gantry-type robot. The problem under consideration employs two horizontal degrees of mobility of one arm and the two corresponding force components. 11 Refs.

**090935 THREE-DIMENSIONAL FLEXURAL-JOINT STIFFNESS ANALYSIS OF FLEXIBLE MANIPULATOR ARMS.** This paper presents a complete derivation of the combined flexural-joint stiffness matrix and the elastic deformation field of flexible manipulator arms treated in a three-dimensional fashion. The stiffness properties are derived directly from the differential equations used in the engineering beam theory. The expressions developed here can readily be used in the modeling, control and design of light weight flexible robot manipulators. A two-link arm is used to formulate these expressions and the results can be generalized to n-link manipulators. The stiffness matrix for a robotic link element in 3-D is of the order of  $12 \times 12$ , and for an n-link robotic arm the total elemental and system stiffness matrices will be of the order of  $(12n \times 12n)$  and  $6(n+1) \times 6(n+1)$ , respectively. **090937 KALMAN FILTERING, SMOOTHING, AND RECURSIVE ROBOT ARM FORWARD AND INVERSE DYNAMICS.** The author points out the equivalence between recursive robot dynamics methods and filtering and smoothing techniques from state estimation theory. The key step is to cast the system dynamics and kinematics as a two-point boundary-value problem whose solution leads to filtering and smoothing techniques similar to the equations of Kalman filtering and Bryson-Frazier fixed-time-interval smoothing. The solutions prescribe an inward filtering recursion followed by an outward recursion. The recursive solutions are of the order  $O(N)$ , in the sense that the number of required computations only grows linearly with the number of links,  $N$ . A technique is provided to compute the relative angular accelerations at all of the joints from the applied external joint moments (and vice versa). It also provides an approach to evaluate recursively the composite multilink-system inertia matrix and its inverse. While the focus is not on exploring computational efficiency, some initial results in that direction are obtained by comparing performance with other recursive methods for a planar chain example. The analytical foundation is laid for the potential use of filtering and smoothing techniques in robot dynamics and control. 20 refs.

**090938 CONTROL OF ARTICULATED ROBOT ARM WITH SENSORY FEEDBACK: LASER BEAM TRACKING SYSTEM.** A method for the trajectory tracking control of an articulated robot arm using sensory feedback is presented. First, a general control algorithm for such a problem is presented. To implement sensory feedback effectively, the dynamics of a robot arm is described in the task coordinate system. Then the dynamics of the robot arm in the task coordinate system are linearized using nonlinear feedback. Because the linearization cannot be done completely because of variations and identification errors of the physical parameters of a robot arm, a robust controller is designed so that the effect of parameter variations and errors can be lessened. The control law is shown to be simplified by the use of high-gain feedback. The simplification can make the implementation of the control law very easy. The proposed algorithm is applied to the trajectory-tracking control of an articulated robot arm using a laser beam. The experiments show that the proposed algorithm works well for such a sensory feedback system. 12 refs.

**090940 ANALYSIS OF ROBOT DRIVE TRAIN ERRORS, THEIR STATIC EFFECTS, AND THEIR COMPENSATIONS.** A mathematical model of the kinematic nonlinear drive-train errors, which reduce the absolute static positioning accuracy of robot arms, is presented. This kinematic inaccuracy renders robot ma-

nipulators less effective when programmed offline, though they might be programmed to successfully perform the same task by teach playback schemes. The kinematic drive-train inaccuracy model presented can be used to predict and compensate for these nonlinear effects online, without resorting to sensor-based programming techniques, which are often expensive and may be difficult to implement in an industrial environment. The drive-train error model presented is based on gear backlash, eccentricity, and drive-shaft compliance. That the effects of these nonlinearities severely impact the robot's repeatability and absolute positioning accuracy is mathematically proven. 9 refs.

**090943 COOPERATIVE CONTROL OF TWO ARMS IN THE TRANSPORT OF AN INERTIAL LOAD IN ZERO GRAVITY.** In designing a robot control system for dual arm configurations, the control engineer is faced with two challenges: to derive the equations of motion for a given situation, and to meet certain desired control requirements (for instance, minimum energy). The former may involve closed kinematic chains, such as the case when the two arms are grasping a common object. The latter usually involves nonlinear optimization. These issues are considered in the context of transporting an inertial load using two planar three-link arms. A generalized 'reduction transformation' is applied to the dynamics to remove the singularity in the system equations. A suboptimal minimum energy method is presented to reduce a difficult 12-state, six-control nonlinear optimization to two independent, nonconflicting suboptimizations. A simulation example is provided to illustrate the degree of energy reduction possible using the optimal arm torque distribution that was developed. 9 refs.

**090944 INDEPENDENTLY WORKING COMPUTER PERIPHERAL GENERATING ROBOT ARM TRAJECTORIES.** An application specific peripheral processor is described, which independently carries out the task of generating the path for the desired motion of a manipulator. The trajectories are planned by the central computer in form of low order polynomial spline functions, whose parameters are transferred to the peripheral. The position, velocity, and acceleration values are

constantly computed to be fed into the manipulator's control system. The algorithms employed by the peripheral and detailed below exploit various intrinsic properties of polynomials to minimize the arithmetic complexity. This distributed logic approach unburdens the central processor and utilizes application specific inherent parallelism. Although a system's internal data transmission expense is reduced, the concept allows higher path update rates. The functional unit can be frequently applied and is thus easily standardizable. (Edited author abstract) 4 refs.

## Assembly

**090945 REQUIREMENTS ON SCREWS FOR AUTOMATIC ASSEMBLY.** In the automatic assembly of screws rationalization effects can be attained only when jointing elements of high quality are guaranteed. During the mass production of screws faults in setting up, sudden and creep-type errors and accidental defects may occur. Sorting by mechanical selection equipment operating with ultrasonics or eddy current induction is faster and more reliable than manual visual checks. (Edited author abstract) 8 refs.

## Balancing

**090946 RESSORTS ET MECANISMES: UNE SOLUTION AUX PROBLEMES D'EQUILIBRAGE.** [Springs and Mechanisms: A Solution to Balancing Problems]. Balancing may be accomplished through the addition of inertia counterweights and restrictions on arm configurations. Irreversible transmission such as screw nut type are also used. To reduce loading characteristics, which can significantly enhance machine process, a new method to balance manipulators by springs is presented. The potential energy storage capabilities of linear springs are integrated with the nonlinear motion of manipulator to provide an exact value of the desired counter loading functions. This is performed by introducing simple mechanism between the spring and the structure to be balanced. Synthesis techniques based on torque balancing and energy method are developed to design the characteristics of mechanism and spring capable of balancing a given structure. Examples are given to demonstrate applications of these procedure and to illustrate the industrial potential of spring balancing. (Edited author abstract) In French. 24 refs.

**090947 MASSENAUSGLEICHSMCHANISMUS FUER INDUSTRIEROBOTER.** [System of Balancing for Industrial Robots]. Balancing of weight forces in industrial robots caused by forces of gravity has a special importance for increasing working speed and improving mass-power ratio, as well as cost reduction of driving energy. In practice, a series of balancing systems have been introduced which work according to different principles. Utilizing energy of a compressed spring in connection with a special crank is the fundamental of a mechanically working balancing system, which has been tested in the industrial robot ZIM 10-A. This article deals with the fundamentals of developing this mechanism. (Edited author abstract) In German. 3 refs.

**090951 LETTING THE INDUSTRIAL ROBOT TAKE THE GRIND.** Bula & Fils produces a varied range of automatic machines for deburring, polishing, buffing, brushing and satin finishing. In addition to its standard series of equipment, it manufactures numerous custom-built models, created and developed in answer to specific technical requirements. The MR250-2 houses an ASEA IRB 1000 six-axis robot and up to three heads to allow for brushing application such as belt grinding. This machine is a multi-purpose surface treatment center for robot handling of complex parts for small-to-medium-size components. Off-line simulation was used to design, test and program robot motion for this new process. This minimized machine downtime and production loss.

**090955 COMPUTER SIMULATION OF SENSOR-BASED ROBOT COLLISION AVOIDANCE IN AN UNKNOWN ENVIRONMENT.** Computer simulation is a major tool in validation of robot motion planning system. This is especially true when the motion planning system in question is based on sensor feedback and the generated trajectory is, therefore, unpredictable. This paper describes a simulation system ROPAS (for Robot Path Simulation) for testing one approach - called Dynamic Path Planning (DPP) - to sensor-based robot collision avoidance in an environment with unknown obstacles. Using real time graphics animation of the motion planning system, the user can simulate the behavior of an autonomous vehicle or a robot arm manipulator with a fixed base. The overall structure of the system is described, and examples are presented. (Author abstract) 15 refs.

**090956 ROBOT SIMULATOR IN TIPS/GEOMETRIC SIMULATOR.** With the growth of factory automation, the need for off-line robot programming is increasing rapidly. Off-line programming requires a robot simulator. This is the reason for the development of a TIPS/GS (Geometric Simulator), accompanied by a robot simulator. TIPS/GS has been developed as a project in the TIPS Research Association. The goal of this project is to extend the functions and applications of the solid modeler TIPS-1. Four simulators (i.e. the assembly simulator, engineering simulator, NC simulator and robot simulator) have been developed for these extended applications. This paper is a report on the development of the robot simulator. (Author abstract) 6 refs.

**090957 DECISION OF ROBOT MOVEMENT BY MEANS OF A POTENTIAL FIELD.** This paper deals with a method of deciding robot movement by means of a potential field and simple simulations using it. In particular, two new concepts, 'state space for a robot' and 'oval potential', are proposed. On the basis of the proposed method, the robot has a potential field in which to store information about its environment. The field is defined on a space that represents the robot's state (state space). By using this field, the robot determines by itself how to move to a goal. The principal concepts of this method are: use of the potential field on a state space in

which the state of the robot is represented by a point enables the decision of movement to be made simply; by using the oval potential for potential distribution, objects are memorized using little information and calculation of the potential values is fast. 3 refs.

**090959 GROSS - GRAPHISCHES ROBOTER-SIMULATIONSPROGRAMM.** [Graphical Robot Simulation Program]. The interactive robot simulation system GROSS is presented that enables the definition and the calculation of robot movements. It supports the simple, fast and sure programming of industrial robots and reduces the necessary time for the development of the control software. The simulation is based on a mechanical model. For a special class of robots (tree structure) any geometrical dimensions can be defined as well as any kinetic and kinematic constraints. The representation of the robot simulation with all essential functions is possible by integration into a 3 D-graphics user interface. The system provides facilities like calculation and control of the working space, collision check with predefined obstacles, storing of all successful actions, estimation of the time for the robot's movements and graphical representation of its movements in real time. (Edited author abstract) In German. 15 refs.

**090960 DISTANCE CALCULATION FOR IMMINENT COLLISION INDICATION IN A ROBOT SYSTEM SIMULATION.** Minimum distance algorithms may be used in robotic simulation programs to provide the user with the distances of approach of the manipulator to obstacles in the work environment; this is important for task planning using graphical simulation of configuration maps, and for the implementation of automatic detection of (imminent) collision in robot task development systems that are based on a graphical simulation facility. In this paper we present algorithms that may be used for the calculation of distances between objects, not necessarily convex, that are made up of unions of convex polyhedra and cylindrically shaped objects (where the cross-section of the cylinder may be ellipsoidal, rather than circular). (Author abstract) 16 refs.

**090963** **TACTILE SENSING IN FLEXIBLE MANUFACTURING CELLS.** Tactile sensing in a flexible manufacturing environment is considered in relation to other developing robot-compatible sensing systems. The versatility of tactile sensing is illustrated and examples of given of the development and application of systems with which the author has been involved. These systems include component capacitance measurement; also component identification and sorting by machining a copy component. As in the use of coordinate measuring machines, a stumbling block is identified in that there is no simple tolerancing system based on generalized variational geometry, combining with geometric model data bases. A step towards zero-defect quality control and reduction in the capital and running costs of flexible manufacturing is through the application of generalized variational geometry. (Edited author abstract) 38 refs.

**090965** **DESIGN OF TACTILE SENSING SYSTEMS FOR DEXTROUS MANIPULATORS.** Preliminary work aimed at understanding the general issues and tradeoffs governing the design of extended tactile sensing systems is reviewed. General methods for estimating the bandwidths of line-addressed and matrix-addressed systems are presented. The proposed tactile sensing system incorporates four subsystems that permit the high-speed access of tactile data: (1) a transduction scheme, which initially will provide binary contact force and location information, but which later will be updated to yield graded force vector data; (2) a preprocessing scheme, which will prepare the data for transmission; (3) a multiplexing and transmission subsystem, which is designed to access the sensory data at speeds proportional to a specified number of sensors; and (4) tactile data selection techniques, which increase the system bandwidth by using a number of user-specified scanning methods. Designs for implementation at each of these levels are presented. The designs emphasize practical necessities such as simplicity, reliability, and economy, along with plans to incorporate a tactile system into the Utah/MIT Dextrous Hand. 29 refs.

**090966** **DIFFERENTIAL SURFACE MODELS FOR TACTILE PERCEPTION OF SHAPE AND ON-LINE TRACKING OF FEATURES.** The online kinematic problem for gliding or rolling on an unknown surface is addressed, treating it as a simple two-rigid-body problem. A planar rigid-body end effector is considered that maintains contact with a rigid body of unknown shape by gliding or rolling on it. The smooth surface of the end effector is assumed to be known implicitly or parametrically in its own coordinate system. The authors present the main results both in equation form and diagrammatically. The figure given implies that if the parameters of the robot are known as well as its state, the forces of contact can be computed. However, due to the extensive amount of data required for this condition to be met, the required sensory and computational machinery may be exorbitant. Moreover, the presence of noise and the cost of removing it sufficiently make this approach impractical at present. 16 refs.

**090971** **ANWENDUNG EINES NEUEN VERFAHRENS ZUR SCHNELLEN UND ROBUSTEN POSITIONIERUNG VON INDUSTRIEROBOTERN.** [Application of a New Concept of Fast and Robust Position Control of Industrial Robots]. There are numerous sophisticated control algorithms for industrial robots (IR) providing perfect results under academic laboratory conditions. The vast majority of IR-control systems on the market prefer rather simple conservative concepts. The main reasons for non-acceptance in practice are the high set-up costs, expensive hardware requirements and poor robustness with respect to parameter variations and model uncertainties. However, sophisticated manufacturing problems of the future (CIM) require more and more a better control performance, a high robustness within a crude industrial environment, more straightforward design and implementation procedures with PC assistance and implementation even on low-price conventional micro hardware. Predictive Functional Control (PFC) represents a new alternative concept for IR-control which can meet the above requirements. In this paper will be reported about the practical application of PFC for the position control of a conventional IR (KUKA 160). The excellent control behavior and robustness will be demonstrated by experimental results and a benchmark test. (Author abstract) 15 refs. In German.

**090972** **CONSTRAINED RELATIONS BETWEEN TWO COORDINATED INDUSTRIAL ROBOTS FOR MOTION CONTROL.** Tasks for two coordinated industrial robots always bring the robots in contact with the same object. Physically the three form a closed kinematic chain mechanism. When the chain is in motion, the positions and orientations of the two robots must satisfy a set of holonomic equality constraints for every time instant. To eliminate motion errors between them, we assign one of them to carry the major part of the task. Its motion is planned accordingly. The motion of the second robot is to follow that of the first robot, as specified by the relations of the joint velocities derived from the constraint conditions. Thus if any modification of the motion is needed in real time, only the motion of the first robot is modified. (Edited author abstract) 9 refs.

**090978 APPROACH TO PARALLEL PROCESSING OF DYNAMIC ROBOT MODELS.** A new parallel-processing scheme for robot dynamics computation on a multiprocessor system is described. The model to be processed is the customized numeric-symbolic dynamic model developed in our previous works, where each element of the dynamic model matrices is computed by an independent procedure (subtask). This feature is very convenient for multiprocessing since the precedence relations are reduced to a minimum. The parallel-processing scheme employs the distribution of subtasks among CPUs according to a modified branch-and-bound method combined with the largest-processing-time-first algorithm. Further, this method is extended to cover the parallel computation of driving torques, once the dynamic model matrices have been computed. The method is illustrated by two examples. (Edited author abstract) 11 refs.

**090982 VARIATIONAL DYNAMIC PROGRAMMING APPROACH TO ROBOT-PATH PLANNING WITH A DISTANCE-SAFETY CRITERION.** An approach to robot-path planning is developed by considering both the traveling distance and the safety of the robot. A computationally-efficient algorithm is developed to find a near-optimal path with a weighted distance-safety criterion by using a variational calculus and dynamic programming (VCDP) method. The algorithm is readily applicable to any factory environment by representing the free workspace as channels. A method for deriving these channels is also proposed. Although it is developed mainly for two-dimensional problems, this method can be easily extended to a class of three-dimensional problems. Numerical examples are presented to demonstrate the utility and power of this method. 13 refs.

**090983 STUDY ON CONCURRENT TASK CONTROL SYSTEM FOR ROBOTS.** The Concurrency Oriented Language COL for robot control and its system are described. In order to construct a Systemized-Robot with high ability by connecting separately developed functions, one has to systematically combine not only the hardware but also the software. On this background, COL has the power and flexibility to describe the following functions: concurrent processing, event control, priority control, shared variable management, real time operation, I/O handling, interrupt handling, and task state control. (Edited author abstract) In Japanese. 1 ref.

**090985 ON THE PLANNING OF COLLISION-FREE MOVEMENTS OF MANIPULATORS.** Up to now, various methods for planning collision-free movements have been proposed. The first half of this paper discusses some of these interesting methods and briefly explains the procedures. Most of these methods are only useful when dealing with limited problems; it is difficult to apply these methods to generalized ones. The second half of the paper deals with the method that generally formalizes the problem of planning collision-free movements and explains it in detail. 31 refs.

**090986 PORT MANIPULATOR FOR THE DISTRIBUTED REALIZATION OF AN INTEGRATED MANUFACTURING SYSTEM.** A new concept, called an integrated multi-robot system (IMRS), for the decentralized control of integrated manufacturing systems was introduced previously. An IMRS is composed of robots, sensors, computers, and other real-time devices. Distributed computing systems are a natural candidate for the production of an IMRS because of their potential for meeting the high performance and reliability requirements. Since inter-communications and real-time performance are crucial to any IMRS, a dedicated function for these, called a port manipulator, is separated from applications. This separation remedies the usual limitation of communication models based on message passing. Implementation of those IMRS communication primitives proposed previously is discussed first, based on ports with various options. A hierarchical structure of the port manipulator is then presented which is suitable for supporting both intramode and intermode communications in the IMRS. The port options enable the IMRS to handle timing constraints in message passing and provide the flexibility of one-to-many, many-to-one and many-to-many mode of communications. **090987 ANALYSIS AND CONTROL OF BIPED LOCOMOTION SUBJECT TO CONSTRAINTS.** In biped locomotion, the double support phase and the single

support phase appear alternately. Thus the form of the system equations frequently switch back and forth between systems of different dimensionality. Therefore the constrained dynamical system plays an important role in the control of the biped robot. The constrained system is analyzed and the control of this system is considered with application to biped locomotion. 15 refs.

**090989 SUBOPTIMAL TRAJECTORY PLANNING ALGORITHM FOR ROBOTIC MANIPULATORS.** This paper presents a Fourier-based suboptimal control approach for the trajectory planning of robotic manipulators modeled as coupled rigid bodies. The basic idea of the method is to convert a standard optimal control problem of infinite dimensionality (in time) into an optimization problem of finite dimensionality by approximating the manipulator trajectories by the sum of a polynomial and a set of appropriate eigenfunctions. The optimal control problem can then be solved via a nonlinear programming numerical algorithm given a performance index which is a continuous function to time. This method can be applied to a large class of problems with different performance indices and requires no model simplification. Manipulator control problems with free time and states and with inequality constraints can be handled effectively. The method is demonstrated in two examples of trajectory planning for a planar robotic manipulator model. (Author abstract) 16 refs.

**090990 MULTISENSORIK FUER EIN ROBOTER-SYSTEM.** [Multisensory System for a Robot System]. Sensors are very important components of advanced robot systems. However, they are difficult to incorporate into robots. For this reason we find only very simple applications in industry. They are usually analog or binary sensors as part of classical control loops. In this paper an architecture for the interpretation of multi sensor data with the help of a knowledge based system is described. The results of the sensor interpretation are the input of the planning process. Thereby, it is possible for the robot to respond to changing working conditions. (Author abstract) 32 refs. In German.

Raczekowsky, J. *Robotersysteme* v 4 n 1 1988 p 53-62.

**090991 TRIAL ON A 6-AXIS FORCE SENSOR FOR ROBOTS.** When automatic working processes such as parts assembling, deburring and grinding, are made by robots, force control must be adapted for their precise work. In such a case, a 6-axis force sensor is indispensable, and it must have the following three characteristics: (i) Compact size and light weight, (ii) High rigidity, (iii) High accuracy and resolution. In order to satisfy these requirements parallel plates structures and radial plates structures are adapted in newly designed 6-axis force sensors. After the investigations, it became clear that they satisfy the above requirements. For example, in case of a B-type detecting block where the rated force is 100 N, rated moment is 10 N·m, it is small (50 mm outer diameter, 44 mm height), light (116 g weight) and rigid (over 1.5 kHz natural frequency) enough. Its final error is smaller than 3% F.S. Its performances are confirmed in several kinds of actual works. (Author abstract) In Japanese. 9 refs.

**090992 APPLICATION OF DISCRETE-TIME MODEL REFERENCE ADAPTIVE CONTROL TO INDUSTRIAL ROBOTS: A COMPUTER SIMULATION.** In this paper a direct approach to discrete-time model reference adaptive control (MRAC) based on hyperstability theory is proposed to control industrial robotic manipulators. For industrial robots and manipulators which usually have highly nonlinear and complex dynamic behaviors and often unknown inertia characteristics, it is very difficult to achieve high performance with conventional control strategies. This high performance in terms of speed and accuracy can be obtained by adaptive control techniques. Considering the effects of gravity, process noise, and payload uncertainty, this approach is investigated using simulation for a three degree of freedom industrial robot. These simulation results show that adaptive control techniques can provide robust properties in spite of poor a priori information regarding the robot dynamics and circumstances. (Author abstract) 15 refs.

**090993 INTEGRATED PLANNING AND EXECUTION CONTROL FOR AN AUTONOMOUS MOBILE ROBOT.** We present a distributed hierarchical planning and execution monitoring system and its implementation on an actual mobile robot. The planning system is a distributed hierarchical domain independent system called FPS for Flexible Planning System. It is a rule based plan generation system with planning specific and domain specific rules. A planning solution to the 'Boxes and Wedge' Problem is presented. The Robot Control System (RCS) operates and monitors the robot in the real world. In order to allow real-time responses to asynchronous events (both internal and external), RCS consists of a rule-based decision kernel and a distributed set of sensor/effector monitors. RCS contains an execution model and may authorize local corrective action, e.g., unexpected obstacle avoidance during execution of a trajectory. RCS also generates status and failure reports through which the PMs inform the different decision subsystems as to the robot's state and current capacities. The failure reports help the RCS and planners in correcting/replanning a plan that has aborted. (Edited author abstract). 34 Refs.

**090994 MINIMUM OPERATIONS AND MINIMUM PARAMETERS OF THE DYNAMIC MODELS OF TREE STRUCTURE ROBOTS.** An efficient method for the calculation of the inverse dynamic models of tree-structure robots is presented. The method significantly reduces the computational burden such that the inverse dynamics can be computed in real time at servo rate and leads almost directly to models with a minimum number of arithmetic operations. The method is based on a Newton-Euler formulation that is linear in the inertial parameters, on an iterative symbolic procedure, and on condensing the inertial parameters by regrouping and eliminating some of them. The description of the robot is carried out by a new notation inspired from J. Denavit and R.S. Hartenberg's (1955) notation. Results of a Fortran program developed to generate automatically the dynamic models of tree-structure robots are discussed. 26 refs.

## Costs

**090997 FINANCIAL EVALUATION OF ROBOTICS INSTALLATIONS.** An important topic in capital equipment acquisition is the analysis of robots in the manufacturing environment. Due to the unique characteristics of robots, it is important to recognize all the costs and benefits of a robotic installation in evaluating the feasibility of including this new piece of equipment in the production process. What makes analyzing the proposed robotic acquisition different from the usual capital equipment purchase is dealing with secondary and tertiary benefits and costs afforded by robotic systems. The chief difficulty is estimating the cost benefits due to the flexibility of the robot installation. Three important and essential steps in the determination of the value of a robotic installation are considered. (Edited author abstract) 5 refs.

**090998 DETERMINATION OF THE PARAMETERS OF THE BALANCING MECHANISM FOR STATIC LOADS ON THE ELBOW OF THE HINGED MANIPULATOR OF INDUSTRIAL ROBOTS.** A mechanism for balancing the static moments at the elbow, with the use of a compression spring, has been developed for any manipulator used in quantity produced industrial robots. The criterion for choosing the optimum parameters of the balancing mechanism for static loads in the elbow is determined by the need to maintain a constant balancing force over the entire range of elbow displacements in a vertical plane. 4 refs.

Kondrin, A.T. *Sov Eng Res* v 7 n 1 Jan 1987 p 2-4.

**090999 DESIGN STRATEGIES FOR HIGH-SPEED LIGHTWEIGHT ROBOTS.** Industrial robots today can lift objects no heavier than about five percent of their own weight. Imagine a robotic weight lifter competing against the current Olympic human record of 750 lb. By today's standards, that robot would have to weigh about 15,000 lb, is opposed to its human competitor, who would weigh 165 lb (and who is 'rated' at 450 percent of body weight). The paper explains how weight loss in the design of a robot brings benefits such as faster and more accurate motion but the hazards could lead to lower performance. The paper describes how this problem can be approached with four design options and shows how each one addressed an important requirement. 9 refs.

**091000 USING EXPERT SYSTEM TO FIND ROBOTIC PATH WITH COLLISION AVOIDANCE.** A rule-based expert system has been developed and applied to a robotic planning system with collision avoidance. The model is represented as knowledge data and stored in the knowledge base with rules. The expert system can find collision-avoidance path. Several examples for different objects to pass through the different channels and to find collision-avoidance paths have been tested. The simulation results give the planning sequence or blocked section(s). The output information is useful for making decision about robot motion and for modifying the technological parameters. (Edited author abstract). In Chinese.

**091001 CONCEPTION MECANIQUE, CINEMATIQUE ET DYNAMIQUE DES ROBOTS.** [Mechanical, Kinematic, and Dynamic Design of Robots]. In this paper, we describe the different models that must be used, from the mechanical point of view, to account for the complex behavior of robots. The model consists of sub-models, each one describing a partial aspect of the global behavior. The main sub-models are respectively concerned on one hand with the geometrical kinematic and dynamic aspects, and on the other hand with actuators dynamics and control laws. Each sub-model is briefly described while the unresolved problems are enumerated. Some examples are shown that give a general overview of what can presently be achieved. #### Efficiency

**091003 EFFICIENCY OF M GROUPS OF N MACHINES SERVED BY A TRAVELLING ROBOT: COMPARISON OF TWO MODELS.** This paper solves the problem of calculating the efficiency of M groups of N machines under the care of one operative (robot), whose way of working is to patrol the groups either uni-directionally or bi-directionally, depending on whether they are located on a circle or on a line. Each group of machines is situated on a rotating circular disk (carousel). This work extends the earlier works for the uni-directional and the bi-directional patrolling problems. The problem arises in the practical context of a textile winding process and has some other industrial applications. Results are of value in maintaining controls and monitoring the process. #### Electric Drive See Also MACHINE TOOLS—Electric Drive.

**091004 DIRECT DRIVE AND WELD SENSORS**

**EMERGE IN TOKYO.** Direct drive (DD) robots, promised by the Japanese for a couple of years, were once again the dominant theme at the International Robots Show in Tokyo, but this time they are starting to go into production. Seiko I&E introduced a cartesian co-ordinate machine which it claims is faster over the standard assembly cycle than any DD robot. NEC, Matsushita and Sankyo Seiki introduced very cheap robots for assembly, while one or two companies are switching to the emphasis of systems rather than individual robots. Laser sensors for arc welding are also coming into vogue, now that Fanuc has succeeded in integrating the Meta Machines device.

**Grippers See Also BIOMEDICAL ENGINEERING—Computer Aided Analysis; ELECTRONIC EQUIPMENT MANUFACTURE—Robotic Assembly; INSTRUMENTS—Errors; ROBOTS, INDUSTRIAL—Sensors.**

**091009 GOALS OF ROBOT GRIPPER MECHANICS.** This paper is devoted to the methods of computation and analysis of equilibrium positions of the object in the robot gripping device, assuming that the contact between the object and gripper is maintained in a finite number of points. Problems of construction of computation models which make it possible to determine the reliability of holding an object in the gripper of an industrial robot in operation are considered. To compute the gripper carrying capacity, the authors developed a procedure involving a system of seven equilibrium equations for the 'object-gripper' mechanical system when the equations are solved, the carrying capacity of the gripper can be estimated and its exhaustive characteristic plotted, which is the area of rigid fixation within the space of acting forces and moments. The results of the present study can be used when developing the robot gripping devices, optimizing their parameters, or estimating the reliability of object holding in auxiliary transfer devices, feeders and positioners (such as spools, dispensers, special holders, etc.). (Author abstract) 3 refs.

**091010 KINEMATICS AND FRICTION IN GRASPING BY ROBOTIC HANDS.** Using the extended screw theory, grasping is analyzed in terms of the complete and partial constraint of a rigid body. The underlying kinematic theory is first reviewed and illustrated. The extended screw theory is then used to determine the disturbing and nondisturbing external wrenches, and resulting disturbances for a grasped object. This is a new application of the concept of total freedom based on the idea of component motions and the wrenches that can cause them. Determining the disturbing and nondisturbing wrenches is tantamount to determining the stability of the grasp in regard to total freedom. Finally, a novel method of incorporating friction in the kinematic analysis of grasping using screw theory is also developed using the concepts of apparent normals and apparent motions. (Author abstract) 11 refs.

**091012 STUDY ON CONTROL OF A MICRO-MANIPULATOR (1ST REPORT, BASIC CHARACTERISTICS OF A MICRO-GRIPPER AND A METHOD OF BILATERAL CONTROL).** A method of the master-slave type of bilateral control as one of the teleoperators is proposed in this paper to improve the operability of a micro-manipulator system for applications to genetic manipulation, micro surgery and others, which require contractive position and force. Conventional bilateral control methods can be classified from the viewpoint of a unified approach and a more general method is proposed here as the impedance reflective control method under some assumptions that the master slave dynamics are both linear. Then the stability problem

is also described in the vein of the model reference adaptive system. The slave of the micro-gripper, as one of micro-manipulators is made of a PMN ceramic actuator and the double link mechanism, while the master is made of a DC motor and an operating lever. (Edited author abstract) In Japanese. 15 refs.

**091017 GRIPS OF INDUSTRIAL ROBOTS FOR THE TRANSFER OF TIRE BEADS.** Proceedings from the requirements that grips have to fulfill, we find that the

basic criteria for choosing the optimal variant are: reliable gripping of the tire bead, ensuring mechanical integrity of the tire bead when gripped, rapid action of the grips, convenient gripping and transfer of the bead, minimal weight of the grip. The selected criteria are most satisfactorily met by mechanical grips where the clamping of the bead is effected with the aid of expanding levers. Since beads are not sufficiently rigid along the outer circumference, they have to be gripped along the inner circumference. This ensures mechanical integrity of the beads when they are gripped. The necessary gripping force on the tire bead by the grip is determined by proceeding from the condition of ensuring removal of the beads from special container cassettes intended for their storage and transport, and holding them in the grip during transfer. A calculation diagram for determining the gripping force applied to the tire bead is presented. The method of calculating the gripping force exerted on beads was used in designing grips for industrial robots used in the transfer of tire bead rings and beads in a complex (system) of machines for making components and assembling car tires. 9 refs.

**091018 RESTRAINT ANALYSIS OF A RIGID BODY USING FRICTIONAL ELASTIC CONTACTS.** This paper presents the analysis of restraint of a rigid body in contact with any arrangement of point contacts having known frictional properties. A necessary condition for the solution of this problem is that the elastic properties of the contacts are also known. The relationship between externally applied loads and contact forces in the presence of limiting friction is established, as is the means for evaluating the resulting bodily motion, with or without slip at the contacts. An example is given to illustrate the application of the theoretical basis to a device such as a robot gripper that relies on friction for restraint. (Author abstract) 15 refs.

**091022 SYNTHESIS OF A SELF-CENTRING ROBOT GRIPPER FROM A PERMISSIBLE BASIC**

**ERROR.** The objective of this paper is synthesis of the gripper mechanism from the permissible basic error. Since the gripper is self-centring, zero is taken as the nominal value of the dimension relative to which the deviations are sought, i.e. relative to points lying on the diameter of the component which is to be clamped. A deviation relative to zero is taken both with a plus sign and with a minus sign. This is necessary in the calculation method described. 2 refs.

**091023 LOW COST TACTILE GRIPPER USING SILICONE RUBBER SENSOR ARRAY.** A low cost tactile sensor using commercially available conductive silicone rubber has been developed. It comprises a two dimensional array arranged in 3 mm centre-to-centre distance. Each sensor element has a zero-force resistance of about 0.3 kohm and it has a logarithmic characteristic curve of resistance versus force. An 8 × 8 prototype tactile sensor array over an area of 3 cm × 3 cm has been fabricated and mounted on the gripper of a robot for testing and evaluation. The associated software has also been developed. The limitations of the sensor are also discussed. (Author abstract) 14 refs.

**091024 GREIFERTECHNIK IN DER GERA-ETECHNISCHEN INDUSTRIE.** [Gripper Technique in the Instrumental Industry]. The gripper technique plays the greatest role in the adapting of manipulators to the manufacturing process beside the software. Derived from typical instrumental and technological requirements, different gripper principles and the motion behaviour of the gripper components are explained. Furthermore the design of the drive technique resulting from this and of the form elements is described. (Author abstract) 12 refs. In German.

Braunschweig, A. (Technische Hochschule Ilmenau, East Ger). *Feingeratetechnik* v 36 n 6 1987 p 251-254.

**091025 SENSORIZED ROBOT GRIPPER.** This paper describes the design, fabrication, and preliminary testing of a tactile sensing array which is the core of a gripper intended for industrial applications. The tactile sensor, consisting of a matrix of 128 sensing elements, is based on the technology of the piezoelectric polymer PVF2. The system comprises a purposely developed electronic unit designed to scan and amplify the signals generated by the tactile matrix. Preliminary experiments demonstrate the ability of the sensorized gripper systems to detect binary tactile images of several different objects. (Edited author abstract) 10 refs.

**091026 OPTIMIZING THE HANDLING OF OBJECTS WITH MULTI-FINGER GRIPPERS.** Considerable effort has been devoted in recent years to the development of effective multiple prehension end effectors for both robotics applications and prosthetic devices. The evaluation of the contact forces between the fingers and the object is the fundamental parameter in designing and controlling end effectors; this is particularly important in handling delicate objects. This article introduces a generalized program which optimizes the grasp action of objects with known geometries by grippers with any number of fingers. The technique is particularly useful in designing end effectors for handling delicate objects. 8 refs.

Badreldin, Ashraf (Univ of Wisconsin, Madison, WI, USA); Seireg, Ali A. *Comput Mech Eng* v 6 n 5 Mar-Apr 1988 p 47-57.

**091027 CONSTRUCTING FORCE-CLOSURE GRASPS.** This paper presents fast and simple algorithms for directly constructing force-closure grasps based on the

shape of the grasped object. The synthesis of force-closure grasps finds independent regions of contact for the fingertips, such that the motion of the grasped object is totally constrained. A force-closure grasp implies equilibrium grasps exist. In the reverse direction, we show that most nonmarginal equilibrium grasps are force-closure grasps. (Author abstract) 17 refs.

Nguyen, Van-Duc (GE, Schenectady, NY, USA). *Int J Rob Res* v 7 n 3 Jun 1988 p 3-16.

**091028 KINEMATICS OF CONTACT AND GRASP.** The kinematics of contact describe the motion of a point of contact over the surfaces of two contacting objects in response to a relative motion of these objects. Using concepts from differential geometry, the author derives a set of equations, called the contact equations, that embody this relationship. He employs the contact equations to design the following applications to be executed by an end-effector with tactile sensing capability: determining the curvature form of an unknown object at a point of contact; and following the surface of an unknown object. The contact equations also serve as a basis for an investigation of the kinematics of grasp. The relationship between the relative motion of two fingers grasping an object and the motion of the points of contact over the object surface is derived. (Edited author abstract) 15 refs.

**091029 INVESTIGATION OF FRICTIONLESS ENVELOPING GRASPING IN THE PLANE.** Grasping by a two-dimensional hand composed of a palm and two hinged fingers is studied. The mathematics of frictionless grasping is presented and used in the development of a planner/simulator. The simulator computes the motion of the object using an active constraint set method and assuming exact knowledge of the physical properties of the polygonal object, hand, and support. Grasping is divided into three phases. During the first phase, the initial grasping configuration is found. In the second phase, the object is manipulated away from the support, bringing it into contact with the palm. In the last phase, the grip is adjusted to minimize the contact forces acting on the object. (Author abstract) 28 refs.

**091031 FLEXIBLE FINGERS CAN SOLVE GRIPPER SENSITIVITY PROBLEMS.** The integrated servo/tactile gripper has been developed to assembly small mechanical devices and odd form or standard electronic components. Yet, it has been designed with features that promote flexibility and are cost effective. The interchangeable finger sets not only provide the needed flexibility in handling a variety of component designs but are inexpensive and easy to fabricate. The integration of two independently controlled parallel movement fingers with six-degrees of force sensing capabilities provide the degree of intelligence necessary to assembly a broad range of devices. Utilising force information to grasp and release allows the gripper to adapt to the component and not vice versa. Components can be inserted with a new level of confidence due to its lead 'jamming' sensing. The gripper system allows the user to relax the requirements for the precise fixturing of components, thus reducing costs. These features allow the user to design flexibility into a robot-based assembly station. 1 refs.

**091032 APPLICATION OF ACOUSTIC EMISSION SENSING TO SLIP DETECTION IN ROBOT GRIPPERS.** This paper discusses the application of acoustic emission signal analysis as a sensing tool for the detection of contact and slip related motion between a workpiece and an end effector. Some results from past work in this area are first reviewed. Different modes of slip motion (rotational and translational) are then discussed. The ability to distinguish between these slip modes is important, since it enables the robot to assess the gripping stability and recover positional control of the workpiece. Experimental results are presented to demonstrate the sensitivity of the detected acoustic emission signal to these different modes of slip motion. The effect of the gripping force on the detected acoustic emission is also discussed. (Author abstract). 17 Refs.

**091033 PLANNING FOR THREE-FINGER TIP-PREHENSION GRASPS.** This paper discusses the planning of grasp configurations for three-fingered tip-prehension grasps. Geometric reasoning is incorporated into the selection process so that the task requirements, together with constraints on compatibility between the task's and the object's geometry, can be used to find feasible grasp configurations. A classification of objects is made, whereby they are divided into groups based on their geometric characteristics. Task requirements are then used for developing selection rules for each group of objects. In addition, methods for reaching a grasp in the existence of uncertainty are suggested. (Author abstract). 16 Refs.

**091037 AUTOMATIC EVALUATION OF TWO-FINGERED GRIPS.** Grip determination is essential to any task-level planning process. The complete force/moment equations are presented for grasping by a rigid two-fingered gripper with a thin elastic layer on the contacting surface. The surface contact is modeled as a linear pressure variation. The quality measure of a grip is taken to be the coefficient of friction needed to keep the held object from slipping between the fingers under applied forces and moments. The lower the coefficient of friction, the better the grip. Incorporation of this evaluation into general grip selection strategy is discussed, and several examples are given. 22 refs.

Barber, James (Univ of Michigan, Ann Arbor, MI, USA); Volz, Richard A.; Desai, Rajiv; Rubinfeld, Ronitt; Schipper, Brian D.; Wolter, Jan. *IEEE J Rob Autom* v RA-3 n 4 Aug 1987 p 356-361.

**091038 TASK-ORIENTED OPTIMAL GRASPING BY MULTIFINGERED ROBOT HANDS.** The problem of optimal grasping of an object by a multifingered robot hand is discussed. Using screw theory and elementary differential geometry, the concept of a grasp is axiomatized and its stability characterized. Three quality measures for evaluating a grasp are then proposed. The last quality measure is task-oriented and needs the development of a procedure for modeling tasks as ellipsoids in the wrench space of the object. Numerical computations of these quality measures and the selection of an optimal grasp are addressed in detail. Several examples are given using these quality measures to show that they are consistent with measurements yielded by the authors' experiments on grasping. 32 refs.

**091039 ANALYSIS OF EQUILATERAL GRIP OF A PRISMATIC AND CONVEX WORKPIECE.** Certain facets of the gripping problem in robotics are discussed. A gripper with a single degree of freedom is considered, which consists of three equal-length fingers. The set of workpieces under consideration are modeled by prismatic and convex polyhedra. This leads to a planar-geometric formulation. The computational geometric problem of inscribing, in a given convex polygon, an equilateral triangle that is locally minimal, is addressed. Feasibility and the (computational) geometric construction of the solution are emphasized. 3 refs.

**091042 MOTION CONTROL ALGORITHMS FOR SENSOR-EQUIPPED ROBOTS.** This paper deals with the development of kinematic algorithms for the control of sensor-equipped robots. The kinematics is solved in the sensor coordinate system, which reduces the computation efforts, and allows the elimination of the first joint encoder. Simplification of the algorithms can be obtained when approximations are used to solve the inverse kinematics. Three control algorithms based on approximations are presented. However, with these algorithms, convergence to the target is not always guaranteed. A Theorem which specifies the sufficient conditions required for a trajectory to converge to a target point is proved. Based on this Theorem robot parameters can be selected in the design stage of the manipulator. This is illustrated for several types of manipulators. (Author abstract) 14 refs.

**091043 DETERMINING OBJECT ATTITUDE AND POSITION FOR BIN-PICKING TASKS GUIDED BY AN INTERPRETATION TREE DERIVED FROM A GEOMETRICAL MODELER.** A method is presented in which the position and the attitude of the object can be determined by interpreting the depth map, needle map, and the edge map, following the interpretation tree. Before a matching is tried, the interpretation tree is derived based on the attitude group. The attitude group classifies the attitudes based on the labels of the observable regions. The branch in the interpretation tree is determined based on the dependence of the label on the set of regions. At each stage, the most favorable feature is utilized for the matching at the branch. The matching feature for each attitude group is employed in the precise determination of the attitude in the attitude group. This information is also registered in the interpretation tree. The input information for matching is the edge map obtained by differentiating the density map, the needle map obtained by the density-difference stereo, and the depth map obtained by the two pairs of density-difference stereo. The matching is made following the interpretation tree and using the most favorable feature at each stage. The description of the determined position, attitude and the background is stored in the world of geometrical model. Using the stored description, safe-grip attitude of the gripper is determined. (Author abstract) 18 refs.

**091044 PLANNING OF ACTIVITY OF ROBOTS IN QUASI-DYNAMIC ENVIRONMENTS.** Three models for organization of purposeful activity of an intelligent robot are considered. In the framework of the first model, the activity of the robot is organized in the presence of complete and accurate information about the

environment. Mechanisms of solution search, representation and use of knowledge to control the search are described. The second model allows functioning of the robot to be organized in an environment about which it has no complete and accurate information. Mechanisms are considered for analysis and identification of states of the environment, correction of knowledge, planning and replanning the activity of the robot. The third model is directed toward organization of joint functioning of a team of robots under conditions where they have common components of the environment. Mechanisms of coordination of activity of the robots with access to common resources are considered. (Author abstract) 3 refs.

**091045 INTEGRIERTES SENSORGESTUETZTES ROBOTERSYSTEM.** [Integrated Sensor Based Robot System]. This paper describes the work of the ESPRIT project 278 which is concerned with the development of an integrated sensor based (tactile and vision) robot system capable of intelligent action within the area of workpiece positioning and orientation, an important class of manufacturing problems. A vision system is used to provide an initial estimate of workpiece position and orientation which allows the robot to grasp the object. During the grasping phase, the tactile sensor confirms, modifies or improves the initial information provided by the vision system. (Author abstract) 5 refs. In German.

Warnecke, H.J.; Lindner, H.; Glaess, W. *Robotersysteme* v 4 n 1 1988 p 1-8.

**091046 KNOWLEDGE-BASED ROBOTICS.** Even if we use techniques such as geometric modelling for representing objects in the robot world, we are still lacking in methods for linking such representations with sensory feedback. In this paper, we have proposed the use of intermediate representations—we call them sensor-tuned representations—for linking constructive solid geometry (CSG) based solid modelling with sensory information. We also discuss how sensor-tuned representations are constructed from range data and how object recognition can be done with sensor-tuned representations. Finally, we show results of manipulation experiments produced by the current implementation of the system. (Edited author abstract) 22 refs.

**091047 ROBOTICS RESEARCH AND DEVELOPMENT CONTINUE TO ADVANCE, ACHIEVING HIGHER LEVELS OF APPLICATION.** The article focuses on the details of industrial robot development in Japan and on trends in production, research, progress and future prospects. Research and development of third generation robots is now under way centering on the most advanced technological efforts. Traditionally, teaching/playback method has always existed between man and robots. In the future, however, although man will retain total control, the robots themselves will be able to process sophisticated environmental information and act according to their own judgment. At that time, only when the robot itself becomes incapable of effecting such judgment, the operator will be asked to judge how best to act in under the circumstances. This will be characterized as a robot-man system.

**091048 INCREASING THE INDUSTRIAL ROBOT'S IQ.** High-level control in which the computer determines the motion path required to accomplish a task (known as intelligent control) is considered. The concepts of artificial intelligence and of a universal machine are examined in this context. Robot programming is then discussed. 2 refs.

Hall, Ernest L. (Georgia Technical Research Inst, Atlanta, GA, USA). *IEEE Potentials* v 6 n 4 p 38-40.

**091049 DYNAMIC MULTI-SENSOR DATA FUSION SYSTEM FOR INTELLIGENT ROBOTS.** The objective of the authors is to develop an intelligent robot workstation capable of integrating data from multiple sensors. The investigation is based on a Unimation PUMA 560 robot and various external sensors. These include overhead vision, eye-in-hand vision, proximity, tactile array, position, force/torque, cross-fire, overload, and slipsensing devices. The efficient fusion of data from different sources will enable the machine to respond promptly in dealing with the 'real world.' Towards this goal, the general paradigm of a sensor data fusion system has been developed, and some simulation results, as well as results from the actual implementation of certain concepts of sensor data fusion, have been demonstrated. 24 refs.

## Japan

**091050 PRODUCTION ENGINEERING LABORATORY, DEPARTMENT OF MECHANICAL ENGINEERING, KYUSHU INSTITUTE OF TECHNOLOGY.** The current state of research at PEL/KIT covering automation and highly accurate production machining technology, especially for robots, has been briefly introduced. In the production field, R&D activities are positively conducted on the basis of the concepts of CAD/CAM and FA in order to rationalize production systems completely, together with the rapid progress in microelectronics and mechatronics technologies. The deburring robot DR-1 has been developed to release operators from work in ill-conditioned environments surrounded by vibration, noise, and dust, where deburring operations of castings are conducted. The measuring robot MR aims at automatically measuring the dimensions of machined workpieces set at an arbitrary position. To recognize the kind of workpiece, MR takes a picture of the workpiece by means of an ITV camera and processes it to obtain the contour. A simplified algorithm allows identification of the workpiece shape which is transferred to the robot. 2 Refs.

## Learning

**091051 ON THE ITERATIVE LEARNING CONTROL THEORY FOR ROBOTIC MANIPULATORS.** An iterative learning technique is applied to robot manipulators, using an inherently nonlinear analysis of the learning procedure. In particular, a 'high-gain feedback' point of view is utilized to prove the possibility of setting up uniform upper bounds to the trajectory errors occurring at each trial. The subsequent analysis of convergence shows that apart from minor conditions, the existence of a finite (but not necessarily narrow) bound on the trajectory deviations can substantially suffice to guarantee the zeroing of the errors after a sufficient number of trials. This in turn leaves open the possibility of obtaining the exact tracking of the desired motion, even in the presence of moderate values assigned to the feedback gains. 16 refs.

Bondi, Paola (Univ di Naples, Italy); Casalino, Giuseppe; Gambardella, Lucia. *IEEE J Rob Autom* v 6 n 2 Feb 1988 p 14-22.

**091052 REALIZATION OF ROBOT MOTION BASED ON A LEARNING METHOD.** To make a robot track a given desired motion trajectory, a learning control scheme is proposed which is based on the repeatability of robot motion. In this scheme the robot obtains a desired motion by repeating trials (test motion). A merit of this control scheme is that the input torque

pattern that generates the desired motion can be formed without estimating the physical parameters of robot dynamics. In practice, to allow the robot motion to approach the desired one in each trial, the input torque given to the robot at the present trial is modified only by the velocity signal of the real robot motion at the previous trial and the desired one. The convergence to the desired motion is theoretically proved for a linear time-varying mechanical system, which is an approximate representation of nonlinear robot dynamics in the vicinity of the desired motion. The effectiveness of this control scheme is demonstrated through actual experiments in which a revolute-type manipulator with three degrees of freedom is used, and the desired motion trajectory is given not only in terms of joint-angle coordinates but also in terms of task-oriented coordinates. 7 refs.

**091060 SYMBOLIC MATRIX MANIPULATION PACKAGE FOR THE KINEMATIC ANALYSIS OF ROBOT MANIPULATORS.** Symbolic matrix manipulations, repetitious and time-consuming, generate many chances for mistakes. A set of computer programs to handle and then review these tasks could be a valuable tool for the engineer.

Driels, Morris R. (Texas A&M Univ, College Station, TX, USA). *Comput Mech Eng* v 5 n 2 Sep 1986 p 38-46.

**091061 NEW GENERAL ALGORITHM FOR DE-**

**SCRIBING MANIPULATOR KINEMATICS.** A new algorithm for representing the kinematic problem of robot arms is presented, and its advantages discussed. It is shown that manipulator links and joints can be described using generalized cascaded 'robot joint descriptors'. Such a description provides a theoretical basis for the development of a kinematic controller applicable to most manipulator geometries. (Author abstract) 3 refs.

**091062 FORCE COMPLIANT MOTION IN A POSITION CONTROLLED MANIPULATOR.** Control of robot manipulators is reviewed with special emphasis on the requirements during fine motion with contact forces. Various approaches to force based control systems are discussed. An approach to force control which can be added on to existing commercial position controllers is presented and an implementation of this scheme is described. The limitations of the approach are pointed out and suggestions for further enhancements made. (Author abstract) 10 refs.

**091063 MANIPULATOR CONTROL USING A DATA-DRIVEN MULTI-PROCESSOR COMPUTER SYSTEM.** A number of schemes employing several conventional computational elements or a conventional processor augmented with special purpose transform processors to control manipulator systems have been used. The computational model underlying conventional computing architectures is itself inadequate and not very useful. Certainly the data communication mechanism in systems using several conventional computational elements is difficult to integrate with the sequential computing model. The study described in this paper applies a computing system based on the Data-flow model of computation to the task of manipulator control. Subjects covered include data flow, computation, task decomposition, and others. 22 refs.

**091064 ON MULTIPLE MOVING OBJECTS.** This paper explores the motion-planning problem for multiple moving objects. The approach taken consists of assigning priorities to the objects, then planning motions one object at a time. For each moving object, the planner constructs a configuration space-time that represents the time-varying constraints imposed on the moving object by the other moving and stationary objects. The planner represents this space-time approximately, using two-dimensional slices. The space-time is then searched for a collision-free path. The paper demonstrates this approach in two domains. One domain consists of two-link planar articulated arms. (Author abstract) 26 refs.

**091065 ON THE EXISTENCE AND SYNTHESIS OF MULTIFINGER POSITIVE GRIPS.** We study the criteria under which an object can be gripped by a multifingered dexterous hand, assuming no static friction between the object and the fingers; such grips are called positive grips. We study three cases in detail: (i) the body is at equilibrium, (ii) the body is under some constant external force/torque, and (iii) the body is under a varying external force/torque. In each case we obtain tight bounds on the number of fingers needed to obtain grip. We also present efficient algorithms to synthesize such positive grips for bounded polyhedral/polygonal objects; the number of fingers employed in the grips synthesized by

our algorithms match the above bounds. The algorithms run in time linear in the number of faces/sides. (Edited author abstract) 25 refs.

**091066 APPROACH TO THE DESIGN OF IDEAL ROBOTIC MANIPULATORS HAVING SIMPLE DYNAMIC CHARACTERISTICS.** The dynamic characteristics of currently used, multi-degrees-of-freedom robots are too complex to analyze and thus, it is not possible to design an implementable control algorithm. This paper proposes the guidelines to use in designing an ideal robot whose dynamics are much simpler than those of the conventional robot. It is shown that, even if the proposed design criteria are fulfilled with respect to the wrist only, the dynamic complexity can be drastically removed so that the conventional robot approaches very close to an ideal robot having simple dynamic characteristics. This paper further shows that the ideally designed robot dynamics can be very easily derived from Lagrangian formulation. (Edited author abstract) 13 refs.

**091067 EXPERIENCE AND OUTLOOKS ON OUR STUDIES ON ROBOTS.** There are many kinds of robots - from a manual manipulator to an intelligent robot - which may be classified by various levels of autonomy. Since a robot is a machine used by human beings, it is essential to make the robot easy to handle. Therefore, it is necessary to adapt the robot to human characteristics. To be able to develop more intelligent robots, we need to study the man-robot interface in more detail. The paper discusses remote control manipulation; computer control of manipulators of a robot arm; introduction of the method of virtual reference; dynamic control; other research concerning the control of manipulators; use of visual information; and locomotion and its combination with vision. 19 refs.

**091069 MODELING AND CONTROL OF ELASTIC JOINT ROBOTS.** In this paper, the author will study the modeling and control of robot manipulators with elastic joints. A simple model to represent the dynamics of elastic joint manipulators is derived under two assumptions regarding dynamic coupling between the actuators and the links, and is useful for cases where the elasticity in the joints is of greater significance than gyroscopic interactions between the motors and links. In the limit as the joint stiffness tends to infinity, our model reduces to the usual rigid model found in the literature, showing the reasonableness of our modeling assumptions. It is shown that our model is significantly more tractable with regard to controller design than previous nonlinear models that have been used to model elastic joint manipulators. **091070 DIGITAL ALGORITHM FOR NEAR-MINIMUM-TIME CONTROL OF ROBOT MANIPULATORS.** A digital state feedback control algorithm has been developed to obtain the near-minimum-time trajectory for the end-effector of a robot manipulator. In this algorithm, the poles of the linearized closed loop system are judiciously placed in the Z-plane to permit near-minimum-time response without violating the constraints on the actuator torques. The validity of this algorithm has been established using numerical simulations. A three-link manipulator is chosen for this purpose and the results are discussed for three different combinations of initial and final states. (Author abstract) 15 refs.

**091071 PATH GENERATION BY RATE CONTROL OF MANIPULATORS.** This paper proposes a real-time control algorithm, in which both the actual errors of position and of orientation are fed back to the control value calculated for each sampling time. This paper also defines the distance between two orientations, and presents a set of formulas for orientational error using quaternions. An algorithm using screw algebra is developed for the real-time computation of joint velocities. Finally, the accuracy of trajectory control using this algorithm is studied experimentally. (Author abstract) 4 refs.

**091072 3D AUTONOMOUS TRAJECTORY CONTROL OF ROBOT MANIPULATORS.** The structure of the three-dimensional autonomous trajectory control system is analyzed as a control system driven by the feedback of the proximity sensory information between the end effector and a spatial curve. The Jacobian matrix of the autonomous trajectory control system is then defined, which includes the information on the spatial curve to be traced. Based on the analysis, a three-dimensional autonomous trajectory control system is synthesized. Simulation results show its effectiveness for improving performance, and also prove that the orientational error does not disappear because of the lack of information on the curvature of the spatial curve. Finally, to improve the orientational characteristics in autonomous trajectory control, a special wrist mechanism is proposed. 17 refs.

**091073 CONTROL OF MOTION OF MANIPULATOR WITH PROXIMITY SENSOR ALONG PROFILE OF OBJECT.** A gantry-type manipulator is considered that is equipped with an optical proximity sensor (OPRS). The two-dimensional motion of the manipulator is studied along the profile of an object whose shape is not known a priori. A control technique is described that yields this motion. An analytic study is made of motion along a straight line and a circle. Stationary motions along these curves are sought and their stability is analyzed. Experiment shows that by such a control technique it is possible to move the manipulator along the profile of objects of complex shape. (Author abstract) 15 refs.

**091074 GENERALIZED INVERSES FOR ROBOTIC MANIPULATORS.** Jacobians are used in robotics for motion planning and control. They are also used in algorithms that determine linkage parameter errors of robots and in algorithms that determine pair variable corrections for accurate motion. Most applications require that the inverse of the Jacobian be obtained. The causes of singularities in Jacobians and a procedure to detect their presence are given. Appropriate inverse solution techniques and their implementation for robots with

various types of singularities is outlined. The solutions are applicable to robots with less than, equal to, or greater than six degrees of freedom. For each case, the implementation of both the complete Moore-Penrose inverse and a robot specific pseudo inverse are included. Although it is not necessary to use the Moore-Penrose inverse on any particular robot, the Moore-Penrose inverse can be used to obtain generic inverses for general purpose applications. (Author abstract) 20 refs.

**091076 EIN SYSTEMATISCHES VERFAHREN FUER DIE RUECKWAERTSTRANSFORMATION BEI INDUSTRIEROBOTERN.** [Systematic Approach for Solving the Inverse Kinematic Problem of Robot Manipulators]. The inverse kinematic problem of robot manipulators requires the computation of the joint coordinates to execute prescribed trajectories. It implies the determination of six dependent joint coordinates in a kinematical multibody loop via six nonlinear algebraic constraint equations. The approach presented in this paper yields a non-redundant system of constraint equations which is always partitioned into an implicit core system and explicitly solvable equations. General rules have been derived for the generation of these equations. For numerous classes of manipulator designs even the complete system of equations can be solved in closed form. The method is applied to the inverse coordinate transformation of a robot with non-orthogonal revolute axes. (Author abstract) In German. 10 refs.

**091078 CARTESIAN CONTROL OF A SPRAY-PAINTING ROBOT WITH REDUNDANT DEGREES OF FREEDOM.** A controller for redundant manipulators with a small, fast manipulator mounted on a positioning part has been developed. The controller distributes the fast motion to the small, fast manipulator and the slow, gross motion to the positioning part. A position reference is generated on-line to the positioning part to avoid singularities and the loss of degrees of freedom. This reference is selected according to an ad hoc procedure which makes the small, fast manipulator work around the centre of its working range. In the control system, the task space position vector is augmented with the generalized coordinates of the positioning part. The

experiments showed that a high bandwidth and a large working range were possible with moderate motor torques, and that the end effector had a higher bandwidth than the positioning part. (Edited author abstract) 21 refs.

**091079 MODELING OF MANIPULATOR DYNAMICS IN THE CASE OF A VIBRATING BASE.** We investigate the dynamics of a manipulation robot with a vibrational stimulus that is transmitted via the base or foundation of the supporting structure of the manipulator. The manipulator is treated as a chain of rigid bodies that are connected in series by rotational or translational pairs, rigidly connected to a base that executes translational and angular vibrations. Control of the robot is constructed with feedback with respect to departures from nominal motion. Numerical and asymptotic methods of calculating the departures of the manipulator motion from the nominal trajectory are proposed. Results of computer modeling of manipulator dynamics are given. (Author abstract) 11 refs.

**091080 ON THE THEORY OF MANIPULATION SYSTEMS WITH FORCE SENSITIZATION.** Force-moment sensitization of robotic systems constitutes a promising line of development in robotics. This paper considers a general mathematical model of a manipulation robot with a force-moment adaptation system. Structural compliance of the manipulator (in the joints and elements) is disregarded. It is assumed that compliance is concentrated only in the force sensors. No constraints whatever are imposed on the kinematic scheme of the structure. We investigate the situation, which arises, e.g., in mechanical-treatment and assembly operations, in which mechanical constraints are imposed on the object of manipulation. We describe a method of control such that the object of manipulation moves along the constraints. This method utilizes information regarding the forces. As an example we consider the problem of assembly of a thread joint. (Edited author abstract) 13 refs.

**091082 DSP BASED NUMERICAL CALCULATION ENGINE FOR MANIPULATOR CONTROL.** A general purpose vector/matrix calculation engine based on a 13.4MFLOPS single chip floating point digital signal processor (DSP  $\mu$ PD77230 has been developed. This engine has been proposed to simplify DSP programming without degrading its high performance computation capabilities. Basic vector/matrix functions and general functions for scalar value computation have been developed and their performance has been measured. To measure actual effectiveness in applications, algorithms for kinematics and control in robotics computation have been implemented on the engine, and their execution time has been estimated. Inverse dynamics for 6 rotational joint manipulators, based on the recursive Newton-Euler equation and with no customization for specific manipulators, has been calculated in under 0.9 msec. An efficient computation algorithm for the Jacobi matrix for the same type manipulators has been derived in under 0.3 msec. An

active stiffness control algorithm has also been computed in under 0.7 msec. This engine can be applied to high-sample-rate real time robot control as a numerical calculation accelerator. (Edited author abstract) 12 refs.

**091084 MULTIVARIABLE SELF-TUNING CONTROL WITH DECOUPLING FOR ROBOTIC MANIPULATORS.** The paper presents two self-tuning control schemes for robotic manipulators, based on two canonical multivariable difference models. The controllers are designed such that the variances of generalized cost functions are minimized and the controller parameters are directly estimated. The weighting factors in the cost function can be prespecified in such a form that the manipulator system is decoupled and closed-loop pole assignment is achieved. Simulation results on a robotic manipulator with three degrees of freedom are presented to demonstrate the effectiveness of, and to make a performance comparison between, these two schemes. (Author abstract) 22 refs.

**091085 GLOBALLY STABLE COMPLIANT MOTION CONTROL FOR ROBOTIC ASSEMBLY.** Compliant control has been proposed as a means of avoiding the expense of highly accurate robots, fixtures and tooling. The Artificial Potential approach is an approach to compliant control which guarantees asymptotic stability but yields little insight into how one might design a controller to meet specific transient behavior specifications. The Robust Compliant Motion approach yields a controller which causes the manipulator to behave like a specified mechanical impedance in a small region of the workspace, but does not ensure stability outside this region. We present design criteria which yield a globally stable controller meeting a target impedance specification in a region about a specified operating point. Our criteria consist of three matrix equations which must be satisfied by position, velocity and feedforward gain matrices. We propose three methods of solving these equations, illustrating one of the methods with an example. We show how the design approach may be extended to redundant manipulators. (Edited author abstract) 14 refs.

**091086 EXPERIMENTAL EVALUATION OF NONLINEAR FEEDBACK AND FEEDFORWARD CONTROL SCHEMES FOR MANIPULATORS.** The manipulator trajectory tracking control problem revolves around computing the torques to be applied to achieve accurate tracking. We present the experimental results of the real-time performance of model-based control algorithms. We compare the computed-torque control scheme with the feedforward dynamics compensation scheme. The feedforward scheme compensates for the manipulator dynamics in the feedforward path, whereas the computed-torque scheme uses the dynamics in the feedback loop for linearization and decoupling. The parameters in the dynamics model for the computed-torque and feedforward schemes were estimated by using an identification algorithm. Our experiments underscore the importance of including the off-diagonal terms of the manipulator inertia matrix in the torque computation. The manipulator control schemes have been implemented on the CMU DD

arm II. (Edited author abstract) 20 refs.

**091087 STABILIZATION OF DESIRED MANIPULATOR ROBOT MOTIONS ON THE BASIS OF A RECURSIVE FORM OF MOTION EQUATIONS.** For manipulators with a complex kinematic behavior the operation speed of the algorithms forming the controls to stabilize a desired motion can be improved by means of recurrence algorithms. Of great interest is the method of analysis of a system of solids that allows viewing the system as a set of independent interacting physical pendulums with variable suspension points. The equations of motion of a manipulator are written in a recursive form. The equations are used to construct an effective stabilization algorithm for desired manipulator motions. 5 refs.

**091089 APPLICATIONS OF DAMPED LEAST-SQUARES METHODS TO RESOLVED-RATE AND RESOLVED-ACCELERATION CONTROL OF MANIPULATORS.** Resolved-rate and resolved-acceleration controllers have been proposed for manipulators whose trajectories are determined by real-time sensory feedback. For redundant manipulators, these controllers have been generalized using the pseudoinverse of the manipulator Jacobian. However, near singular configurations, these controllers fail in that they require infeasibly large joint speeds. A damped least-squares reformation of the problem gives approximate inverse kinematic solutions that are free of singularities. This paper defines the new controllers and proves their stability. Some aspects of the behavior of the new resolved-rate controller are illustrated in simulations. (Edited author abstract) 21 refs.

**091090 TRACKING CONTROLLERS FOR ROBOT MANIPULATORS: A HIGH GAIN PERSPECTIVE.** We propose a controller for the path tracking problem of robotic manipulators. The proposed controller structure is similar to that of the computed-torque scheme widely known in the literature. Unlike the computed-torque scheme, this controller is robust with respect to parameter uncertainty and disturbances. The robustness is given by a high gain mechanism that works in conjunction with a nonlinear precompensator in the control loop. The fundamental action of the high gain is to minimize the effective uncertainty that remains, subsequent to any cancellation by the precompensator. Comparison of the performance of

this controller with two other schemes reported in the literature suggests that it performs as effectively. (Edited author abstract) 13 refs.

**091093 IMPLEMENTATION OF ADAPTIVE TECHNIQUES FOR MOTION CONTROL OF ROBOTIC MANIPULATORS.** This paper is concerned with the digital implementation and experimental evaluation of two adaptive controllers for robotic manipulators. The first is a continuous time model reference adaptive controller, and the second is a discrete time adaptive controller. The primary purpose of these adaptive controllers is to compensate for inertial variations due to changes in configuration and payload, as well as disturbances, such as Coulomb friction and/or gravitational forces. Experimental results are obtained from a laboratory test stand, which emulates a one-axis direct drive robot arm with variable inertia, as well as a Toshiba TSR-500V industrial robot. Experimental results from the test stand indicate that these adaptive control schemes are promising for the control of direct drive robot arms. (Edited author abstract) 23 refs.

**091096 SYNTHESIS OF A MINIMUM-TIME MANIPULATOR TRAJECTORIES WITH GEOMETRIC PATH CONSTRAINTS USING TIME SCALING.** The minimum-time and subminimum-time joint trajectories of manipulators with geometric path constraints are planned in consideration of physical constraints based on kinematics and dynamics. The idea of time scaling is introduced, i.e. a time scale factor  $K(t)$  and a set of joint trajectories, called reference trajectories, are used to describe all the sets of trajectories tracing the specified geometric path. The desirable factor  $K(t)$  which makes the travelling time as short as possible is obtained by two proposed methods: the first one is an iteratively improving method using B spline, and the second one is a directly minimizing method. These two methods are preferably applied to a geometric collision-free path of a manipulator. (Author abstract) 8 refs.

**091098 OPTIMUM KINEMATIC DESIGN OF A PLANAR THREE-DEGREE-OF-FREEDOM PARALLEL MANIPULATOR.** In this paper, the design of a planar three-degree-of-freedom parallel manipulator is considered from a kinematic viewpoint. Four different design criteria are established and used to produce designs having optimum characteristics. These criteria are (a) symmetry (b) the existence of a nonvanishing workspace for every orientation of the gripper (c) the maximization of the global workspace, and (d) the isotropy of the Jacobian of the manipulator. The four associated problems are formulated and their solutions are derived. Two of these require to resort to numerical methods for nonlinear algebraic systems. Results of optimum designs are also included. (Author abstract) 14 refs.

**091101 CO-ORDINATE DETERMINATION AND PERFORMANCE ANALYSIS FOR ROBOT MANIPULATORS AND GUIDED VEHICLES.** The paper describes a technique to determine and to track the three-dimensional 'world' coordinates of a point in space, relative to some defined datum. The work was initiated in order to track the location of a robot manipulator end effector, but has relevance to automatic guided vehicles and other applications. A prototype system has been built and evaluated, and has been used successfully to track the tip of a robot manipulator arm moving at velocities of up to 2 m/s within a working envelope consisting of a cube of side 2 m. Measurement resolution of 0.5 mm was obtained, and a sampling rate of 300 Hz was achieved, by the use of real-time software within the measurement system. The coordinates and the velocity outputs are computed in only 1.2 ms. The technique provides accurate tracking of end-effector position, which can be used both for evaluating the dynamic performance of existing controllers and for the synthesis of new forms of control. (Edited author abstract) 7 refs.

**091102 ON VELOCITY AND ACCELERATION OF MANIPULATOR CHAINS.** Quaternions have been successfully used for describing orientation of a rigid body, for attitude transformation and control as well as for investigation into general characteristics of the angular motion of a rigid body. Among all kinds of kinematical equations, the kind of equations in terms of quaternions appears to be the most advantageous one. This paper presents a method using the  $3 \times 4$  short form quaternion matrix for analysis of the angular motion of a rigid body, which is then proved to be superior to the others. In the second part, two transformation algorithms are proposed for deriving the transformation relationships of a body vector. This method is an extension of the passive transformation and active transformation for a space vector introduced by H. Goldstein. Such an extension appears to be very efficient and satisfactory for calculating the velocity and acceleration of rigid body points. Finally, the two above mentioned algorithms are applied to analyze the velocity and acceleration of manipulator chains. (Edited author abstract) In Chinese. 7 refs.

**091103 AUTONOMOUS TRAJECTORY GENERATING SERVOMECHANISM WITH ORIENTATION CONTROL OF END-EFFECTOR.** As a high accuracy trajectory control technique for manipulators, the Autonomous Trajectory Generating Servomechanism (ATGS) has been proposed. Since the function of ATGS in the algorithm is to recover trajectories when they deviate from the specified paths, and the rate-servomechanism in the ATGS is inherently capable of restraining the influence of disturbances by the effect of feedback, the path drawn by the trajectory is robust against the effects due to the dynamics of manipulators and/or parameter changes of systems. The ATGS is extended to the spatial curve case. A trajectory-generating method including the orientation control of end-effector is presented. The

trajectory control method is implemented and tested in a real articulated manipulator. The experimental results have confirmed the effectiveness of the method proposed in this research. (Edited author abstract) 2 refs.

**091104 MULTIVARIABLE CONTROL OF ROBOT MANIPULATORS.** Since manipulators are highly nonlinear, coupled multivariable systems, multivariable control approach is necessary in principle for high speed and accurate operation of manipulators. Multivariable control approaches to robot manipulators are outlined. Then decoupling control, which is one of the multivariable control approaches, of hydraulically driven robots is described. A construction method of an autonomous contouring control system is explained for a two-joint hydraulic robot. (Author abstract) 18 refs.

**091105 VOICE CONTROL FOR A ROBOT - AN EXAMPLE OF A MANIPULATOR FOR THE DISABLED.** Most of the present voice recognition systems adopt a speaker-dependent method which expects the speaker's voice to be preregistered in its memory. And they use a contacting type microphone to cut out background noise. They are not 'good' man-machine interfaces, since they apply some kind of restriction upon the user to cover their technological limitations. In such a way, we must consider both the robots' needs and the limitations of voice recognition in constructing the man-machine interface. This paper, through an example of a voice-controlled manipulator for the upper-limb disabled, discusses the problems that have to be solved before a voice input and output system can be applied to the human-robot system. 6 refs.

**091106 ON THE INVERSE KINEMATICS OF REDUNDANT MANIPULATORS.** Many conventional nonredundant manipulators have singular configurations, near which some small motions of the end-effector require excessive and physically unrealizable joint speeds. Consequently, the usable workspace of the manipulator is effectively reduced. It has been proposed that high joint speeds could be avoided by introducing redundant joints and using an appropriate kinematic inversion algorithm. For a very general class of kinematic inversion algorithms, the theorems of this paper state some fundamental relations between the properties of the algorithm and its ability to resolve such problems. These results have practical implications in the design of controllers for redundant manipulators, especially when real-time sensory input is used to modify the manipulator's trajectory. (Author abstract) 23 refs.

**091107 NEW APPROACH FOR KINEMATIC RESOLUTION OF REDUNDANCY.** This paper deals with the trajectories of points embedded in a moving rigid body being guided by a linkage having extra or 'redundant' motion parameters. A new method for the kinematic use of redundancy is presented. The method is based on the concept of a metric and differs from the typically used pseudo-inverse formulation. It is shown how the redundancy can be used to alter first-order properties such as the shape of the velocity ellipse (or the ellipsoid) and a scalar measure of transmission ratio or effectiveness. It is shown how such local use of the redundancy leads to some global results such as determining the alterable regions and the boundaries of the trajectories. An example of a planar 3R manipulator illustrates these new techniques. (Author abstract) 26 refs.

**091108 OPTIMAL KINEMATIC DESIGN OF 6R MANIPULATORS.** A fundamental theorem for the kinematic design of robot manipulators is formulated and proved. Roughly speaking, the theorem states that a manipulator having six revolute joints is optimal if and only if the manipulator or its kinematic inverse is an elbow manipulator. By 'optimal' we mean a manipulator that has the properties of (i) maximal work-volume subject to a constraint on its length and (ii) well-connected workspace - that is, the ability to reach all positions in its workspace in each configuration. The notion of work-volume we use is that derived from the translation-invariant volume form on the group of rigid motions. This notion of volume is intermediate between those of 'reachable' and 'dextrous' workspace and appears to be more natural in that it leads to simple analytical results. (Author abstract) 18 refs.

**091110 MATHEMATICAL MODEL OF ROBOT MANIPULATION SYSTEMS.** The object of developing a mathematical model of robot manipulation systems is to obtain equations describing the equilibrium and motion of a mechanical rod system consisting of deformable straight or curved links. With the use of the mathematical model described, one can effect the choice of simple cyclic industrial robots for automatic assembly of complex products, proceeding from specified requirements for the accuracy of reproduction of motions when displacing and joining components. An assembly system developed on the basis of these robots successfully performs the required operations. It is distinguished by simplicity of the construction, low cost and functional reliability. 5 refs.

**091112 NEW CLASS OF CONTROL LAWS FOR ROBOTIC MANIPULATORS. PART 1. NON-ADAPTIVE CASE.** A new class of exponentially stabilizing control laws for joint level control of robot arms is introduced. It has recently been recognized that the nonlinear dynamics associated with robotic manipulators have certain inherent passivity properties. More specifically, the derivation of the robotic dynamic equations from Hamilton's principle gives rise to natural Lyapunov functions for control design based on total energy considerations. Through a slight modifications of the energy Lyapunov function and the use of a convenient lemma to handle third-order terms in the Lyapunov function derivatives, closed-loop exponential stability for both the set point and tracking control problem is demonstrated. In

general, the new class of control laws offers alternatives to the more conventional computed torque method, providing trade-offs between computation and convergence properties. Furthermore, these control laws have the unique feature that they can be adapted in a very simple fashion to achieve asymptotically stable adaptive control. (Edited author abstract) 21 refs.

**091113 NEW CLASS OF CONTROL LAWS FOR ROBOTIC MANIPULATORS. PART 2. ADAPTIVE CASE.** A new class of asymptotically stable adaptive control laws is introduced for application to the robotic manipulator. Unlike most applications of adaptive control theory to robotic manipulators, this analysis addresses the nonlinear dynamics directly without approximation, linearization, or ad hoc assumptions, and utilizes a parameterization based on physical (time-invariant) quantities. This approach is made possible by using energy-like Lyapunov functions that retain the nonlinear character and structure of the dynamics, rather than simple quadratic forms, ubiquitous in adaptive control literature, which have bound the theory tightly to linear systems with unknown parameters. It is a unique feature of these results that the adaptive forms arise by straightforward certainty equivalence adaptation of their non-adaptive counterparts found in Wen and Bayard (1988) - i.e. by replacing unknown quantities by their estimates - and that this simple approach leads to asymptotically stable closed-loop adaptive systems. (Edited author abstract) 19 refs.

**091115 SYNTHESIS OF THE CONTROL OF MANIPULATOR ROBOTS BASED ON THE DECOMPOSITION PRINCIPLE.** The paper provides a basis for the use of the decomposition principle for synthesizing control systems for manipulator robots. The essence of the decomposition principle is to use the control to eliminate completely the dynamic interaction among the manipulator links and then to select this control (which eliminates the interaction) so that the manipulator robot will execute motions in accordance with the control goal. The paper establishes that the effect of the decomposition is attained by introducing relay feedbacks. As a result, one obtains a two-level hierarchical control system. The lower-level subsystem ensures the steering of the manipulator toward motion in the decomposition mode, while the upper-level subsystem realizes the coordination of the motions of the links in accordance with the control goal. The structure and parameters of the system do not depend on the properties of the environment nor on the parameters of the manipulator and, in particular, on the mass of the transported load. (Author abstract) 9 refs.

**091116 OPTIMIZATION OF CONTROL MODES IN MANIPULATOR ROBOTS WITH ENERGY EXPENDITURES TAKEN INTO ACCOUNT.** Controls that are optimal with respect to combined functionals and

take into account the energy expenditures of the drive, the time of execution of transport operations and (or) the accuracy of positioning are constructed for a manipulator with electromechanical drives. These controls are designed on the basis of a simplified model which does not take into account the dynamic interaction of the different degrees of freedom. Numerical modeling on the basis of a complete model shows that, for electromechanical manipulators the drives of which contain gear boxes with high gear ratios, the constructed controls ensure high accuracy of steering from an arbitrary initial state to the specified final state. (Author abstract) 17 refs.

**091123 ADAPTIVE FORCE CONTROL OF ROBOT MANIPULATION WITH CONSIDERATION OF CHARACTERISTICS OF OBJECTS (2ND REPORT, CONTROL OF ONE DEGREE-OF-FREEDOM MANIPULATOR BY THE ADAPTIVE HYBRID FORCE CONTROL).** In this paper, a force control method for manipulators is presented with consideration given to object dynamics based on the adaptive control. This method for the manipulator system is an extension of the previously proposed method for gripper systems, with additional consideration given to the mass effect at the tip of the manipulator. Since present industrial robotic manipulators commonly employ the input/output position servo control system, one of the purposes of this study is to use the proposed control system to simultaneously control the position of the manipulator, the forces on the manipulator and the forces against given objects. However, it is not easy to control the manipulator, without knowledge of the objects, because the dynamics of the object inevitably comes into the overall feedback control system. Then, it is necessary to adjust the control gains, depending on handling of the objects. (Edited author abstract) 10 refs. In Japanese.

**091125 DEVELOPMENT OF A PNEUMATIC CONTROL SERVO MANIPULATOR (1ST REPORT, DESIGN AND EVALUATION OF THE DIRECT FLOW-CONTROL VALVE).** For many assembly operations, a robot hand is required to have dexterity, achieved by position, force and compliance control of high degrees of freedom, as well as tactile sensing. The pneumatic servo control, which was used by the authors to control the force and compliance of artificial fingers and an elbow, did not result in a sophisticated movement with a high response. This problem comes from the lack of airflow control in the conventional pneumatic servo valve. A new type of pneumatic servo system, developed in this study, comprises two analog airflow valves with an electromagnetically driven plunger. Analysis and evaluation of the system are conducted, and examples are given to show how to design an electro-pressure transformer using the system, and to show the force and compliance control of the manipulator-joints. (Author abstract) In Japanese. 9 refs.

**091126 ANALIZA WLASNOSCI MANIPULATORA ROBOTA RIMP-1000 I ADAPTACYJNE ALGORYTMY STEROWANIA JEGO RU-**

**CHEM.** [Analysis of Properties of Robot Manipulator RIMP-1000 and Adaptive Algorithms for Continuous Path Control]. In the paper, models of the mechanical arm and of the hydraulic actuators of robot RIMP-1000 are presented. Identification of these models was carried out on the basis of results of a series of experiments. The static and the dynamic properties of this manipulator are investigated. Under the working conditions (sampling period, trajectories to follow) one can assume static dependence of the velocity of movement of each joint upon the input current of a servo-valve. The parameters of this relation are not constant. They depend upon the manipulator load, oil pressure and other variables. However, the form of this dependence is complex and not easy to identify. On the basis of the above property three simple decentralized adaptive control algorithms for continuous path control (CPC) are formulated. (Edited author abstract) In Polish. 10 refs.

**091127 MODELING OF DYNAMICS OF MANIPULATORS WITH ELASTIC JOINTS.** The aim of this paper is to develop an algorithm for automatic generation of a mathematical model of a three-dimensional manipulator, this model then being used to solve problems of dynamic and kinematic manipulator control. A number of studies have developed algorithms of this type under the assumption that the manipulator is a system of rigid bodies (rigid model). Current precision requirements for manipulation robots make it necessary to allow for effects stemming from elastic compliance of their structure. On this basis, we consider a model of a manipulator with absolutely rigid elements and elastic couplings. The resultant semianalytic method of investigation makes possible a complete analysis of manipulator dynamics and requires fewer computational resources as compared to the approach based on the finite-element method. (Edited author abstract) 10 refs.

**091128 ON MODELING OF THE DYNAMICS OF AN ELASTIC MANIPULATOR.** In investigating the dynamics of anthropomorphic manipulation robots, the effect of elasticity of the structure on the accuracy of performance is taken into account. In this paper, we consider a six-element manipulation robot that is mounted, in the general case, on a moving base. We take account of bending and torsional elastic strains of two elements (the remaining elements are assumed to be rigid rods), and compliance of the joints. We obtain a mathematical model of the manipulator involving representation of the solution as a series in eigenfunctions. We give equations for investigating a closed system, with allowance for the dynamic properties of the control motors. (Edited author abstract) 7 refs.

Chernyavskaya, S.S. *Mech Solids* v 22 n 3 1987 p 38-44.

**091129 SYNTHESIS OF CONTROLS FOR A MANIPULATION ROBOT USING LYAPUNOV'S DIRECT METHOD.** Lyapunov's direct method is employed to solve the problem of synthesizing controls and of investigating the stability of a manipulator with drives at a point of the programmed trajectory. The results we present are oriented toward solution of the problem of compensation of external stimuli. For the sake of being definite, we consider a manipulator with electric drives and armature control; however, this does not limit the possibilities for considering some other type of drive. The theoretical results enable us to investigate the dynamics of the complete mathematical model of a manipulation robot, and to set up control laws that implement programmed motion with the requisite accuracy. Construction of a dynamic model in tensor form makes it possible to avoid the technical difficulties that are usually encountered.

tered when Lyapunov's direct method is applied directly to the investigation of multiply connected systems. 5 refs.

**091130 LAGRANGIAN FORMULATION OF THE DYNAMIC MODEL FOR FLEXIBLE MANIPULATOR SYSTEMS.** This paper presents a procedure for deriving dynamic equations for manipulators containing both rigid and flexible links. The equations are derived using Hamilton's principle, and are nonlinear integro-differential equations. The formulation is based on expressing the kinetic and potential energies of the manipulator system in terms of generalized coordinates. In the case of flexible links, the mass distribution and flexibility are taken into account. The approach is a natural extension of the well-known Lagrangian method for rigid manipulators. Properties of the dynamic matrices, which lead to a less computation, are shown. Boundary-value problems of continuous systems are briefly described. A two-link manipulator with one rigid link and one flexible link is analyzed to illustrate the procedure. (Author abstract) 19 refs.

**091133 FAST ALGORITHM FOR INVERSE KINEMATIC ANALYSIS OF ROBOT MANIPULATORS.** To solve the inverse kinematics problem, the authors obtain with little effort a reduce and complete set of equations by a convenient choice of end-effector frame and application of rotation orthogonality. This approach does not require computation of the forward kinematics and can be used with manipulators of any geometry, although it is most efficient when applied to orthogonal manipulators, a class of robot arms defined in this paper. For manipulators requiring numerical techniques, but for which knowledge of one joint variable allows closed-form solutions of the remaining joint variables, an iterative inverse kinematic method, simple and fast enough to be suitable for real-time manipulator control, has been developed. (Edited author abstract) 15 refs.

**091135 DYNAMIC BEHAVIOUR OF A SCARA ROBOT WITH LINKS SUBJECTED TO DIFFERENT VELOCITY TRAJECTORIES.** The dynamics of a mechanical manipulator have the inherent characteristics of being highly non-linear and strongly coupled due to the interaction of the inertial, centripetal, coriolis and gravitational forces. These characteristics produce difficulties in predicting the dynamic behavior of a given manipulators' structure. These interactive forces depend largely on the geometrical configuration and operational conditions of a manipulator. Therefore, it is essential to investigate the dynamics behavior under different conditions in order to obtain an optimal design. This paper presents a study of the dynamics behavior of a robot's arm with particular reference to the mechanical manipulator being designed by the AEAC. A computer software package has been developed to facilitate the investigation of the potential dynamics behavior of a robot's arm and provides the designer with useful information for the real time control of high performance robots. (Edited author abstract) 10 refs.

**091136 GLOBALLY ASYMPTOTICALLY STABLE 'PD+' CONTROLLER FOR ROBOT MANIPULATORS.** We describe a globally stable tracking controller for robot manipulators. The controller is an extension of Takegaki and Arimoto's position controller to the tracking case where a theorem of Matrosov is used to prove its stability. A feature of this controller is its resemblance to the computed torque controller with the inertia matrix outside the position and velocity feedback loops. Thus, our controller is decomposed into an inner PD loop and an outer dynamic compensation loop. This structure allows simple PD computations to be run at a higher speed than the dynamic compensation loop in digital implementations. (Edited author abstract) 12 refs.

Paden, Brad (Univ of California, Santa Barbara, CA, USA); Panja, Ravi. *Int J Control* v 47 n 6 Jun 1988 p 1697-1712.

**091137 HYBRID TWIST AND WRENCH CONTROL FOR A ROBOTIC MANIPULATOR.** Three necessary conditions derived from classical geometry are proposed to evaluate formulations for the simultaneous twist and wrench control of rigid bodies, and for any theory to be meaningful it must be invariant with respect to (1) Euclidean collineations, (2) change of (Euclidean) unit length, and (3) change of basis. It is demonstrated in this paper that a previously established theory of hybrid control for robot manipulators is in fact based on the metric of elliptic geometry and is thus noninvariant with respect to (1) and (2). A new alternative invariant formulation based on the metric of Euclidean geometry and an induced metric of projective geometry is presented in terms of screw theory. An example of insertion illustrates both the invariant and noninvariant methods. (Author abstract). 16 Refs.

**091138 RELIABILITY ANALYSIS OF ROBOT**

**MANIPULATORS.** A probabilistic approach to robot kinematics is presented and the concept of manipulator reliability is introduced to obtain a better evaluation of the performance of manipulators. Techniques are presented to compute this reliability and its relationship to the geometric parameters such as tolerances and arm configuration is discussed. The aspects of accuracy and repeatability of manipulators are explained in terms of manipulator reliability. The reliability of a two-link planar manipulator and the Stanford arm are considered for numerical illustration. (Author abstract). 19 Refs.

**091139 OCCLUSION AVOIDANCE OF VISUAL SENSORS BASED ON A HAND-EYE ACTION SIMULATOR SYSTEM: HEAVEN.** We have developed a hand-eye action simulator system called HEAVEN. This system provides model-based functions to assist the hand-eye system in visual recognition and monitoring the robot environment. This paper describes a function of assisting cameras in occlusion avoidance to input adequate image data without occlusion. The problem to select the best viewpoint for a camera is defined as to evaluate the viewpoints on a geodesic dome generated around a target object model. Occlusion-free space is obtained as regions on the geodesic dome by using a depth buffer algorithm. Then distance transformation of the occlusion-free regions gives candidates of the best occlusion-free viewpoint. Experimental results using a camera-in-hand system demonstrate the usefulness of the HEAVEN system in planning occlusion avoidance. (Edited author abstract). 18 Refs.

**091140 MULTI-VARIABLE CONTROL OF ROBOT MANIPULATORS.** Since manipulators are highly nonlinear, coupled multivariable systems, multivariable control approach is necessary in principle for high speed and accurate operation of manipulators. Multivariable control approaches to robot manipulators are outlined. Then decoupling control, which is one of the multivariable control approaches of hydraulically driven robots, is described. A construction method of an autonomous contouring control system is explained for a two-joint hydraulic robot. (Author abstract). 18 Refs.

**091141 VOICE CONTROL FOR A ROBOT-AN EXAMPLE OF A MANIPULATOR FOR THE DISABLED.** This paper, through an example of a voice-controlled manipulator for the upper-limb disabled, discusses the problems that have to be solved before a voice input and output system can be applied to the human-robot system. At JPL (Jet Propulsion Laboratory), supported by NASA, and VA (Veterans Administration), a voice-controlled manipulator and wheelchair are being developed. The number of voice commands is about 50 and these are used to control the motion of the manipulator and the wheelchair. At VA, the main emphasis is on voice controls at this moment, but they are also using signals produced from head, chin, and eye movements. 6 Refs.

**091142 FORCE DETECTION AND ACTIVE POWER ASSISTANCE OF A DIRECT-DRIVE MANIPULATOR.** When a manipulator is handled manually, it is necessary to reduce the reaction force caused by inertia, friction, gravity, etc. This paper describes an active power assistance system for a direct-drive manipulator, which assists the handling force with a motor, and a force detection system for that purpose. This method detects the

handling force by a combination of motor torque detection with a motor current and rotation detection with internal sensors (tachogenerator, etc.). It does not need special force sensors. Some configurations of the power assistance system are also shown. The effectiveness of the proposed method is demonstrated by feasibility experiments. (Author abstract). 11 Refs.

**091143 ROPE HANDLING BY A ROBOT WITH VISUAL FEEDBACK.** Visual information is necessary for a robot to be able to manipulate flexible objects such as a rope because flexible objects change their shape during motion. Actually direct visual feedback and verification in three-dimensional space are the keys to performing successful manipulation of such flexible objects. In this paper, important problems in hand-eye coordination are discussed and a rope handling experiment is described. The hand-eye system consists of a robot vision system, a general purpose manipulator and a Lisp system. The main visual functions adopted in the experiment are local image processing along a linear region and stereo vision. The experiment involves the performance of tasks such as inserting a rope into a ring and tying a rope. By coordinating the general purpose arm with stereo vision, our robot succeeds in manipulating a flexible rope. (Author abstract). 10 Refs.

**091144 ELECTRIC MOTOR DRIVE MULTILINK MANIPULATOR FOR CORE INTERNAL INSPECTION.** Fuji Electric has developed a large electric motor-drive multilink manipulator system. This system makes it possible to inspect in detail structures in a reactor. This system is composed of a power manipulator, a monitoring manipulator, inspection device and a control system. With simple and easy operation, the system can automatically access the in-reactor structures to be inspected through the narrow space, avoiding the interceptive structures. This report describes an outline of the Manipulator. (Edited author abstract). In Japanese.

**091145 ALGORITHMS FOR OPTIMAL CONTROL OF AN ELASTIC MANIPULATION SYSTEM WHEN PERFORMING TECHNOLOGICAL POWER OPERATIONS.** The problem of finding an optimal control algorithm for an industrial robot which performs a power operation of surface machining is considered. A criterion which takes into account the deviations of the manipulator end point from the programmed displacements as well as the power indices serves as the selection criterion of the optimal control. The optimal control is found by the maximum principle. The methodology proposed for finding optimal control algorithms is examined on an example of a two-stage manipulator which performs a power operation. (Author abstract). 16 Refs.

**091146 MATHEMATICAL MODELING OF THE MECHANICS AND OF THE CONTROL PROCESSES OF MANIPULATION ROBOTS.** Methods for modeling the geometric, kinematic and dynamic interconnections to which manipulation robots (MRs) are subjected and the processes of identification and adaptive control are presented. The concepts of attainability and controllability of MR states are introduced and theorems which yield constructive algorithms for the construction of regions of attainability and controllability and for investigating the control capabilities of MRs are obtained. A algorithm for finding the direction of descent in the solution of the inverse problem of kinematics and trajectory planning is constructed. Its computing complexity is linear in the degrees of freedom. Various algorithms for constructing the equations of MR motion on the basis of

d'Alembert's principle are presented, their computing complexity is investigated, and special transformations for its reduction are introduced. Algorithms for the adaptive control of MR motion which uses both position and force-moment feedback are developed. (Edited author abstract). 18 Refs.

**091148 SERVOCOMPENSATION OF DISTURBANCES IN ROBOTIC SYSTEMS.** Robot manipulators are susceptible to external disturbances that may alter their behaviour so significantly that certain specifications cannot be maintained. Additive signals that satisfy a linear differential equation with constant coefficients are the type of disturbance that may enter a manipulator and corrupt its behaviour. From linear servocompensator theory one knows that linear disturbances can be asymptotically rejected if the linear plant satisfies certain criteria. However, for robot manipulators, which are extremely non-linear, the former criteria cannot be applied. It is shown that linear disturbances can be asymptotically rejected by employing a standard linear servocompensator. In linear system theory the proof that the error  $e \rightarrow 0$  as  $t \rightarrow \infty$  is shown via the Laplace transform. The Volterra series is utilized to verify the asymptotic convergence of the error. Digital computer simulations are carried out on a two-link planar robot to demonstrate the effectiveness of the linear servocompensator. (Edited author abstract). 16 Refs.

**091149 APPLICATION OF DISCRETE-TIME MODEL REFERENCE ADAPTIVE CONTROL TO INDUSTRIAL ROBOTS: A COMPUTER SIMULATION.** A direct approach to discrete-time model reference adaptive control (MRAC) based on hyperstability theory is proposed to control industrial robotic manipulators. For industrial robots and manipulators which usually have highly nonlinear and complex dynamic behaviors and often unknown inertia characteristics, it is difficult to achieve high performance with conventional control strategies. This high performance in terms of speed and accuracy can be obtained by adaptive control techniques. Considering the effects of gravity, process noise, and payload uncertainty, this approach is investigated using simulation for a three degree of freedom industrial robot. These simulation results show that adaptive control techniques can provide robust properties in spite of a poor a priori information regarding the robot dynamics and circumstances. **091150 COMBINATION PARAMETRIC RESONANCE LEAD TO PERIODIC AND CHAOTIC RESPONSE IN TWO-DEGREE-OF-FREEDOM SYSTEMS WITH QUADRATIC NON-LINEARITIES.** The dynamic response of a parametrically excited non-linear system with two degrees of freedom is studied. The system of equations, which describes the compliant motion of a robotic manipulator, exhibits internal resonance and is excited at a frequency near a primary resonance. The effect of coupling is studied in detail. Non-zero periodic motions are observed to co-exist with a stable equilibrium state over a range of detuning near the

resonant frequency. Loss of stability of the periodic response is observed at points of vertical tangency (corresponding to a jump in the response), while for some of the cases, Hopf bifurcation in the response corresponding to amplitude-modulated motions is observed. In the latter case, period-doubling of the amplitude of response is observed with a monotonic change in detuning, eventually leading to chaotic motion in the system. (Edited author abstract). 13 Refs.

**091151 ADAPTIVE HIERARCHICAL CONTROL FOR ROBOTIC MANIPULATORS.** This paper presents a new method of robot manipulator hierarchical control based upon on-line trajectory generation and decentralized pole-placement feedback deduced from the computed torque method. An anticipatory action is included in the controller by insuring subsequent desired joint positions, velocities and accelerations in the Newton-Euler equations of motion. The gains of the decentralized regulators are approximated by simple laws and when found inadequate (i.e. when the difference between desired and real trajectories is measured positions and velocities. New joint reference trajectories are calculated to be more adapted to the situation detected by the sensors. This robot system enables the manipulator to move in a non-predefined way. The adaptive feature of the algorithm improves the robustness of the controller with respect to errors in the dynamic model of the manipulators. (Edited author abstract). 20 Refs.

**091152 KINEMATICS OF COMMON INDUSTRIAL ROBOTS.** An approach to finding the solution equations for simple manipulators is described which enhances the method of Paul, Renaud, and Stevenson, by making use of known decouplings in the manipulator kinematics. This reduces the set of acceptable equations from which we obtain relationships for the joint variables. For analyzing the Jacobian, such decoupling is also useful since it manifests itself as a block of zeros, which makes inversion easier. This zero lock can be used to obtain a concise representation for the forward and inverse Jacobian computations. The decoupling also simplifies the calculations sufficiently to allow us to make good use of a symbolic algebra program (MACSYMA) in obtaining our results. Techniques for using MACSYMA are described. Examples are given for several industrial manipulators. (Edited author abstract). 14 Refs.

**091153 FEEDBACK-ERROR-LEARNING NEURAL NETWORK FOR TRAJECTORY CONTROL OF A ROBOTIC MANIPULATOR.** A neural network model for generation of motor command was proposed in our earlier paper. This model contains a feedback loop (transcortical loop), an internal neural model of motor system (spinocerebellum and magnocellular part of the red nucleus) and an internal neural model of inverse dynamics of the motor system (cerebro-cerebellum and parvocellular part of the red nucleus). The inverse-dynamics model is acquired by heterosynaptic plasticity using feedback motor command (torque) as an error signal. In this paper, we apply hierarchical arrangement of the transcortical loop and the inverse-dynamics model for learning trajectory control of an industrial robotic manipulator. Although neither strict modeling of the manipulator nor precise parameter estimation was required, the control performance by the neural-network model improved gradually during 30 minutes of learning. Once the neural-network model learned to control some movement, it could control quite different and faster movements. That is, the neural-network model has capability to

generalize learned movements. Advantages of the neural-network control over conventional control methods are discussed. (Author abstract). 29 Refs.

**091154 NEW FOUR-LINK MANIPULATOR MECHANISM DESIGNS OFFER ENHANCED LOAD-CARRYING CAPACITY.** Actuators of heavy-duty manipulators (heavy and extra-heavy classes, GOST Standard 25685-83) must satisfy not only general requirements, such as providing the required number of degrees of freedom, avoiding 'dead zones' in the entire range of travels and rotation angles, and having a stiff transmission, with minimum weight and a sealed construction, but also an important specific requirement: a long travel with heavy loads. In meeting this requirement, it is not easy to achieve the requisite stiffness. The best solution is to provide the manipulator with an actuator device having a closed-loop transmission based, for example, on a hinged parallelogram (four-link mechanisms), which in its major plane is largely relieved of bending moments from the weight of the load. 5 Refs.

**091156 TRAJECTORY CONTROL OF MANIPULATORS WITH TIME VARYING INERTIA LINKS.** One way to increase the flexibility (or versatility) of manipulators is to use links with time varying inertia. One can then control both the joint torques and the inertias of the links therefore more pliancy in the practical utilization of the arm. The paper deals with the Lagrangian formulation of the corresponding inertia control problem which can be considered either in open loop or in closed loop form. The general equations are derived and it is shown that one so obtains a set of uncoupled Riccati differential equations which define the dynamics of the structural inertias. Problems related to stabilization and to structural parameter uncertainty are also considered. (Author abstract). 7 Refs.

**091158 B-SPLINES JOIN TRAJECTORY PLANING.** This paper describes how B-splines can be used to construct joint trajectories for robot manipulators. The motion is specified by a sequence of Cartesian knots, i.e., positions and orientations of the end effector of a robot manipulator. For a six joint robot manipulator, these Cartesian knots are transformed into six sets of joint variables, with each set corresponding to a joint. Splines,

represented as linear combinations of B-splines, are used to fit the sequence of joint variables for each of the six joints. A computationally simple recurrence formula is used to generate the B-splines. This approach is used to establish the mathematical model of trajectory generation for robot manipulators, and offers flexibility, computational efficiency, and a compact representation. (Edited author abstract). 19 Refs.

**091159 REDUNDANCY RESOLUTION OF SERIAL MANIPULATORS BASED ON ROBOT DYNAMICS.** Based on the minimization of the joint driving forces/torques, the classical Lagrangian technique is used to develop the governing equations for the computation of the joint accelerations in an N degree of freedom serial manipulator. Explicit equations for the computation of the joint accelerations are developed and used instead of numerical based solutions for pseudo inverses (e.g. singular value decomposition method). The developed solution is computationally three times more efficient than the comparable solutions in the literature. The problems of reliability and stability are discussed. Several modifications are introduced to make the algorithm reliable and stable. An eleven degrees of freedom, three-dimensional robotic manipulator is used in a numerical example to test the developed algorithms. (Author abstract). 22 Refs.

**091160 STATIC AND DYNAMIC LOAD CONTOURS FOR ROBOT LIMIT DESIGN.** Ever since its rapid growth in the industries, there has been a lack of understanding of robot specification. Terms such as payload, accuracy and repeatability are well used by robot manufacturers and practitioners alike but there is no uniformity of conditions under which these terms are defined. This paper deals with static and dynamic load contours within a given workspace, for specifying and designing an all-revolute robot's application. Algorithms to compute repeatability/accuracy contours in workspaces of all-revolute robots will also be introduced. 25 Refs.

**091161 SINGULAR PERTURBATION APPROACH TO CONTROL OF LIGHTWEIGHT FLEXIBLE MANIPULATORS.** The control lightweight flexible manipulators is the focus of this work. The flexible manipulator dynamics is derived on the basis of a Lagrangian-assumed modes method. The full-order flexible dynamic system does not allow the determination of a nonlinear feedback control as for rigid manipulators, since there are not as many control inputs as output variables. This drawback is overcome by a model order reduction, based on a singular perturbation strategy, where the fast state variables are the elastic forces and their time derivatives. **091163 EXPERIMENTS IN LOAD-ADAPTIVE CONTROL OF A VERY FLEXIBLE ONE-LINK MANIPULATOR.** An adaptive control algorithm based

on the self-tuning regulator concept has been experimentally demonstrated on a very flexible one-link robotic manipulator. The lightly-damped structural resonances of the manipulator coupled with the use of a primary sensor separated from the actuator by flexible structure (non-collocated sensor and actuator) to give good accuracy in tip positioning make high-performance controllers sensitive to modeling error. The adaptive controller is able to maintain precise tip position control despite wide variations in end effector load. An identification algorithm is employed which estimates the mass of the tip load. It makes use of a simple parameterization of system transfer functions which is a linear-fractional expression in the mass of the load. The linear quadratic gaussian synthesis procedure is used for control design, a polynomial interpolation to a precalculated table of controller gains is made on-line to implement a controller appropriate to the identified value of load mass. Rate of convergence of the identification algorithm is such that the system is able to adapt to a 40% change in moment of inertia during a single commanded step change in position. (Edited author abstract). 10 Refs.

**091164 DYNAMIC ANALYSIS AND COMPUTER IMPLEMENTATION OF MANIPULATORS BASED ON GENERALIZED D'ALEMBERT'S PRINCIPLE.** The dynamic methods of multi-rigid-body manipulators have become more and more developed. One category derives dynamic equations using vector mechanics or analytical mechanics, such as the T.R. Kane method and Roberson-Wittenburg method. Another category, such as the Popov method searches the constrained extremum of the system using variational principles. It is found that to date no one has attempted to deal with the two categories with an unified approach. The author applies the Gauss principle, the principle on which the Popov method is established, to deduce the dynamic equations of the Kane and RW methods. It is shown that these three methods are all based on the generalized D'Alembert's principle. (Edited author abstract). 8 Refs. In Chinese.

**091167 REDUNDANCY RESOLUTION OF MANIPULATORS THROUGH TORQUE OPTIMIZATION.** Methods for resolving kinematic redundancies of manipulators by the effect on joint torque are examined. When the generalized inverse is formulated in terms of accelerations and incorporated into the dynamics, the effect of redundancy resolution on joint torque can be directly reflected. One method chooses the joint acceleration null-space vector to minimize joint torque in a least squares sense; when the least-squares value is weighted by allowable torque range, the joint torques tend to be kept within their limits. Methods using only the pseudoinverse with and without weighting by the inertia matrix are presented. The results show an unexpected stability problem during long trajectories for the null-space methods and for the inertia-weighted pseudoinverse method, but more seldom for the unweighted pseudoinverse method. Evidently, a whiplash action develops over time that thrusts the endpoint off the intended path, and extremely high torques are required to overcome these natural movement dynamics. 32 refs.

**091169 AUTOMATIC GRASPING: AN OPTIMIZATION APPROACH.** A method is introduced for locating stable grasps with articulated mechanical hands. A metric called the grasp goal function represents the 'distance' to an unstable grasp for a given position, external load, and set of joint torques of the gripper. The process of locating a stable grasp is treated as an optimization problem for which the most stable grasp is found by maximizing the grasp goal function. Physical constraints, such as torque or motion limitations, are accounted for by the incorporation of potential functions in the objective function. Two-dimensional and three-dimensional simulations were undertaken for which objects were represented as polygons/polyhedral and gripper elements as ellipses/ellipsoids. Results indicate that the method is particularly useful for estimating stable grasps when the initial estimate is close to being stable, but that it also can often perform adequately when this is not the case. In some instances, inadequate grasps are obtained due to the presence of local optima which represent unstable grasps, but it is still felt that the method will have application in future automated systems as a low-level component. 14 refs.

**091171 STATE AND PARAMETER ESTIMATION FOR ROBOTIC MANIPULATORS USING FORCE MEASUREMENTS.** A general framework is proposed for incorporating both a priori task geometry information and online observations, including force measurements, into an optimal estimation algorithm. The output of the algorithm is state and parameter estimates that serve to disambiguate the task geometry and can be used to dynamically adapt subsequent motions. The problem is formulated as a nonlinear constrained dynamical system, including Coulomb friction between the system and the constraints. The constraint surface is described with respect to some unknown parameters representing the geometric uncertainty. The noisy online state and force observations are expressed as functions of the state and surface parameters. The extended Kalman filter is then used to produce optimal estimates of the state and surface parameters. 15 refs.

**091172 DYNAMIC HYBRID POSITION/FORCE CONTROL OF ROBOT MANIPULATORS - DESCRIPTION OF HAND CONSTRAINTS AND CALCULATION OF JOINT DRIVING FORCE.** For the application of robot manipulators to complex tasks, it is often necessary to control not only the position of a manipulator but also the force exerted by the hand on an object. For this purpose, M. H. Raibert and J. J. Craig proposed the hybrid position/force control method (1981). In this method, however, the manipulator dynamics are taken into account rigorously. The dynamic hybrid control method, which takes the manipulator dynamics into consideration, is proposed. Constraints on the end effector are described by a set of constraint hypersurfaces, and the basic equations for dynamic hybrid control are derived. It is shown that if the manipulator is not in a singular configuration, the desired position and force at the end effector can be simultaneously realized. A basic structure of the dynamic hybrid control system with a servo compensator is given. 11 refs.

**091175 COST-EFFICIENT HIGH-PERFORMANCE BIT-SERIAL ARCHITECTURE FOR ROBOT INVERSE DYNAMICS COMPUTATION.** A novel cost-efficient parallel and pipelined bit-serial array architecture is proposed for its computation that achieves

a certain bit-serial execution-time lower bound. The core of the system consists of two arrays of multifunctional bit-serial cells. One of the arrays computes the forward iterations, and the other one evaluates the backward recursions of the Newton-Euler dynamics algorithm. At the current state of technology, the resulting high-performance system may be realized in only two custom VLSI chips and a minimum number of first-in-first-out register files. The organization, operation, and performance of the proposed array structure is discussed. The architecture and functionality of an individual multifunctional bit-serial cell used as the building block of the array structure is described.

**091176 LANGRANGIAN DYNAMICS OF FLEXIBLE MANIPULATORS USING ANGULAR VELOCITIES INSTEAD OF TRANSFORMATION MATRICES.** An approach that uses angular velocities and  $3 \times 3$  rotation matrices to represent link kinematics efficiently is presented. A truncated method expansion is used to model link deflection. A recursive computational procedure is presented that is similar to the Newton-Euler dynamics formulation for rigid manipulators. The full nonlinear inverse dynamic equations are calculated in recursive form for manipulators with an arbitrary number of flexible links. Kinematics are computed recursively from the base to the tip, and torques are computed on the return recursion. On the basis of this formulation, a fast and accurate simulation algorithm is presented. It is shown that this method offers significant improvement in computational speed without degrading numerical accuracy. The modeling accuracy of the method and some practical implementation problems are discussed.

**091177 POSITIONING ERROR ANALYSIS FOR ROBOT MANIPULATORS WITH ALL ROTARY JOINTS.** Industrial robots can be commanded to accomplish different tasks with program sequences that are executed in digital computers. The operating software within these computers can provide users with information on positions and orientations of the end effectors by computing them as functions of the joint variables. However, these functions are generally not exact enough with the result that differences between the computed and the actual positions can be significant. Error sources that contribute to these differences for robots with rotary joints are examined. The effects of these errors are parameterized, and measurement data are fitted to obtain the values of these parameters. It is concluded that with sufficient but not exhaustive detail in the error modeling the differences can be reduced significantly from 5.9-mm mean error with nominal model down to 0.28-mm mean error after error compensation. 11 refs.

**091178 PIPELINED COMPUTATION OF MANIPULATOR MODELING MATRICES.** The authors describe a characterization of the inertia content in the control formulation for the nonlinear, time-varying system of a robotic manipulator. The characterization is in the form of a pipelined modeling software which is implemented on a medium-sized array processor to run in real time. The time-varying inertia content of the manipulator is expressed in terms of kinematic influence coefficients which are represented by explicit functions of only the generalized coordinates. Properties of these influence coefficients are used to reduce the computation effort necessary to generate the modeling coefficients. The resulting algorithm requires a large number of small vector and matrix operations. To efficiently pipeline this algorithm, the structure inherent in the problem is

exploited to allow extensive use of data-dependent addressing which is used to compute multiple 'small' operations within a single pipeline. The resulting software consists of two portions—an offline portion generates integer offset vectors to direct the addressing of the online portion in computing the modeling coefficients. 40 refs.

**091179 NEW CONTROLLER DESIGN FOR MANIPULATORS USING THE THEORY OF VARIABLE STRUCTURE SYSTEMS.** A controller design for manipulators using the theory of variable-structure systems (VSS) is presented to deal with the set-point regulation problem. The major obstacle of VSS vector control with strong dynamic coupling is overcome for a class of systems with positive symmetric inertia matrices. Parameter variations can easily be considered in the design methodology, which is readily extendable to a higher number of links. The problem of chattering is solved by the introduction of sliding sectors. 9 refs.

**091180 OPTIMAL PARAMETRIZATION OF CURVES FOR ROBOT TRAJECTORY DESIGN.** A numerical method is presented for the offline determination of the minimum-time parameterization of a fixed path in robot joint space, assuming start and end at rest conditions and subject to constraints on manipulator joint torques. A numerical method for solving the problem is discussed in which the derivative of the change of variables is approximated by a cubic spline. Numerical results for a three-axis manipulator are presented. 14 refs.

Marin, Samuel P. (GM, Warren, MI, USA). *IEEE Trans Autom Control* v 33 n 2 Feb 1988 p 209-214.

**091181 UNIVERSAL SIX-JOINT ROBOT CONTROLLER.** The authors describe the specifications, design, and implementation of a general-purpose six-axis robotic manipulator controller developed to serve as a research tool for investigating practical and theoretical aspects of control strategies in robotics. The 80286-based Intel System 310 was used for running the XENIX operating servo software as well as higher-level software that implements kinematics and path planning. A Multibus-compatible interface board was designed and constructed to handle input/output signals from the joint motors of the robot manipulator. The universal controller is capable of driving robot manipulators equipped with electric joint motors and position optical encoders. To test functionality, the controller was connected to the joint motor DC power amplifier of a Unimate PUMA 560 arm, bypassing completely the manufacturer-supplied Unimate controller; proportional-integral-derivative (PID) control laws were installed into the XENIX operating system. Additional software drivers were implemented to allow application programs access to the interface board. All software was written in the language C. 9 refs.

**091182 DEXTEROUS WORKSPACE OF SIMPLE MANIPULATORS.** A theoretical study on the dexterous workspace of robotic manipulators is presented. For a robot with wrists that can generate a full range of orientations, the boundary of the robot's dexterous workspace is governed by the boundary of  $W_1(4)$ , where  $W_1(4)$  is the reachable space of joint 4 when joints 1-3 are free to rotate. A method is developed on this basis. Three examples are given to illustrate this concept and method. They show that for simple robots, analytical expressions for the dexterous workspace can be obtained. 18 refs.

**091183 NEW METHOD OF DYNAMICS FOR ROBOT MANIPULATORS.** A novel method of dynamics for robot manipulators has been developed from Lagrangian mechanics. This method can solve the problem in which the number of computations is numerous when the Lagrange-Euler method is used for deriving a set of closed and explicit-form differential or state equations for robot manipulators. The method can be applied to the design of control systems, the dynamic simulation, and the computation of generalized forces or torques of robot manipulators. The number of computations of using this method is small enough to allow real-time computation on a minicomputer or microcomputer. The whole computational process for deriving the complete dynamic equations of a robot manipulator with  $n$  degrees of freedom requires at most  $(3n^3/2 + 14n^2 + 79n/2 - 4)$  multiplications and  $7n^3/6 + 10n^2 + 115n/3 - 10$  additions. 14 refs.

**091184 SYNTHESIS OF SMOOTH TRAJECTORIES FOR PICK-AND-PLACE OPERATIONS.** A spline-based method of programming smooth trajectories for pick-and-place operations is introduced. Unlike continuous-path operations, which impose a unique Cartesian trajectory, an infinite number of smooth trajectories can be described between any given pick and its corresponding place configuration. The method begins with the mapping of the pick and the place configuration in Cartesian space into joint-coordinate space, using a general-purpose inverse kinematics package that handles singularities and redundancies. Next, a trajectory, composed of a  $C^2$ -continuous, periodic cubic spline segment, is defined between the pick and the place configurations in the joint-coordinate space. It is demonstrated that  $C^2$ -continuity will prevail in Cartesian space as well. The software implementing this method includes a graphics package as well as an interface to an offline programming system to realize the synthesis of the actual robot motion. Details of the procedure are illustrated with a numerical example applied to a commercial industrial robot. 21 refs.

**091185 TIME-OPTIMAL CONTROL FOR A ROBOTIC CONTOUR FOLLOWING PROBLEM.** A mathematical formulation for the time-optimal contour following problem, defined by a unilaterally constrained manipulator, is presented. The formulation includes a careful development of the manipulator dynamics and of conditions for avoidance of impact between the end effector and the constraint surface. By a priori specification of the paths for the unconstrained motion segments, a parameterization approach is used to simplify the optimal control formulation, so that solution procedures can be identified. The methodology is applied to a simple contour-following problem for a planar Cartesian manipulator. 9 refs.

**091186 KINEMATICS OF SPATIAL ROBOTIC BEVEL-GEAR TRAINS.** A systematic approach is developed for the kinematic analysis of multi-degree-of-freedom robotic bevel-gear trains. The approach is based on the idea that the motion of a bevel-gear-type end effector can be described by an equivalent open-loop chain and that the relative rotation between every two adjacent links in the equivalent open-loop chain can be derived from a set of fundamental circuit equations and coaxial conditions. The theory is demonstrated by the kinematic analysis of two robotic wrists. 17 refs.

Tsai, Lung-Wen (Univ of Maryland, College Park, MD, USA). *IEEE J Rob Autom* v 4 n 2 Apr 1988 p 150-156.

**091187 ANALOG MATRIX INVERSION.** The enhancement of robot dynamic performance can be aided by high-speed and, in some cases, low-accuracy calculation of

matrices and their inverses. Analog techniques for the calculation of robot kinematics are reviewed and a method for fast matrix inversion is proposed. Tradeoffs in speed and accuracy in such computations are also examined. 12 refs.

**091188 DYNAMICS AND SIMULATION OF COMPLIANT MOTION OF A MANIPULATOR.** A rigid body model for compliant motion of a manipulator is derived. The model is formulated in the joint coordinate frame, and then transformed into the constraint frame to reduce the dimensionality of the model. The proposed model is useful in the simulation of force-controlled manipulators. Examples considering the tasks of a 'peg in a hole' and 'turning a crank' are given. The basic structure of the model is represented in a general framework applicable to many other constrained mechanical systems. A control architecture is suggested, which according to the model leads to exact decoupling of force and position-controlled directions. 27 refs.

Kankaanranta, Raimo K. (Tampere Univ of Technology, Finl); Koivo, Heikki N. *IEEE J Rob Autom* v 4 n 2 Apr 1988 p 163-173.

**091189 MINIMUM TIME TRAJECTORY PLANNER FOR THE DISCRETE DYNAMIC ROBOT MODEL WITH DYNAMIC CONSTRAINTS.** A minimum-time trajectory-planner is proposed for a manipulator arm. A totally discrete approach is adopted, in contrast to other models which use continuous-time but resort to discretization in the computation. The Neuman and Tourassis discrete-dynamic robot model is used to model the robot dynamics. The proposed trajectory planner includes joint-torque constraints to fully utilize the joint actuators. Realistic constraints such as the joint-jerk and joint-velocity constraints are incorporated into the model. The nonlinear optimization problem associated with the planner is partially linearized, which enables the iterative method of approximate programming to be used in solving the problem. Numerical examples for a two-link revolute arm are presented to demonstrate the use of the proposed trajectory planner. It is numerically verified that the convergence of the iterative algorithm is quadratic, and the trajectory planner therefore is computationally efficient. The use of a near-minimum time-cost function is also shown to yield a solution close to that obtained with the true minimum time-cost function. 13 refs.

**091190 MANIPULATOR KINEMATICS AND THE EPSILON ALGEBRA.** An algebra is defined for use in problems of manipulator kinematics. With this algebra, one can program the solution to the kinematics in position problems, and use this same program to solve the kinematics problems in velocity and acceleration. The inverse kinematics part of the program can be used to obtain any order time-derivative of the joint positions. Some of the properties of the algebra are shown and functions of the elements of the algebra are defined. The solution to the forward and inverse kinematics problem is presented, and the use of the Ada programming language is discussed. 15 refs.

**091191 AUTOMATIC GENERATION AND SYNTHESIS OF C-FRAMES FOR MECHANICAL PARTS IN AN INSERTION TASK.** An approach that utilizes the geometric information about the mating parts in generating and synthesizing the C-frame and the compliance-selection vector which are needed at every sampling instant for hybrid position/force control scheme in an insertion task, is presented. A geometric modeling

system is used to model the mating objects involved in the insertion task. From the geometric model of the objects and the nominal position-trajectory of the task, a set of cut-planes of the mating objects perpendicular to the insertion direction can be obtained. Each individual cut-plane provides the freedom direction and the rotation freedom information of the peg on that plane. By combining the freedom directions and rotation freedom information, the orientation of the C-frame and the compliance-selection vector needed to control the manipulator to complete the insertion task can be determined. Due to the uncertainties inherent in working with real-world objects, and the limited position accuracy of the manipulator, an uncertainty model is incorporated into the cut-planes to reflect the position and orientation uncertainties of the C-frame. This approach reduces a difficult three-dimensional problem into a set of two-dimensional problems and will successfully complete the task even in the presence of position and orientation uncertainties. 11 refs.

**091192 DIRECT-DRIVE ACTIVE COMPLIANT END EFFECTOR (ACTIVE RCC).** A fast, lightweight, active end-effector, which can be attached to the endpoint of a commercial robot manipulator, has been designed and built using an impedance-control method. This control method causes the end-effector to behave dynamically as a two-dimensional remote center compliance (RCC). The compliance in this active end-effector is electronic and can be modulated by an online computer. The device is planar and five-bar linkage, and is driven by two direct-drive, brushless DC motors. A two-dimensional, piezoelectric force cell on the endpoint of the device, two 12-bit encoders, and two tachometers on the motors form the measurement system. The high structural stiffness and light weight of the material used in the system allow for a 15-Hz-bandwidth impedance control. 21 refs.

**091193 SUBTASK PERFORMANCE BY REDUNDANCY RESOLUTION FOR REDUNDANT ROBOT MANIPULATORS.** The problem of selecting joint space trajectories for redundant manipulators is considered. Solutions which allow secondary tasks to be performed by the arm simultaneously with end-effector motions may be selected in a number of ways. An algorithm to accomplish this, by means of conditions on a scalar function of the joint variables, is introduced and analyzed. Problems inherent in schemes involving constraints in configuration space are considered. 15 refs.

**091195 ON THE DYNAMIC CHARACTERISTICS OF A BALANCED PUMA-760 ROBOT.** To reduce complexities in robot dynamics, a mechanical counter-balancing concept based on the theory of adding balancing masses to unbalanced conventional manipula-

tors is introduced. The effects of balancing on the dynamic characteristics of the PUMA-760 robot when the designed counter-balancing mechanism is applied to the robot are examined. Through theoretical and experimental study many distinct advantages such as simplicity in the dynamic equation and significant reduction in the total required input torques are demonstrated for various manipulator speeds and payload conditions. Based on these results, the dynamic characteristics of the balanced PUMA-760 robot are discussed in detail. 20 refs.

**091196 EFFICIENT PARALLEL ALGORITHMS FOR ROBOT FORWARD DYNAMICS COMPUTATION.** Two efficient parallel algorithms for computing the forward dynamics for real-time simulation were developed for implementation on a single-instruction multiple-data-stream (SIMD) computer with  $n$  processors, where  $n$  is the number of degrees of freedom of the manipulator. The first parallel algorithm, based on the composite rigid-body method, generates the inertia matrix using the parallel Newton-Euler algorithm, the parallel linear recurrence algorithm, and the modified row-sweep algorithm, and then inverts the inertia matrix to obtain the joint acceleration vector at time  $t$ . The time complexity of this parallel algorithm is of the order  $O(n^2)$  with  $O(n)$  processors. Further reduction of the order of time complexity can be achieved by implementing the Cholesky's factorization procedure on very-large-scale-integrated (VLSI) array processors to invert the symmetric, positive-definite, inertia matrix. The second parallel algorithm, based on the conjugate gradient method, computes the joint acceleration with a time complexity of  $O(n)$  for multiplication operation and  $O(n \log_2 n)$  for addition operation. The interprocessor communication problem for the implementation of the proposed parallel algorithms on SIMD machines is also discussed and analyzed. 17 refs.

**091197 EXPLORATION OF SENSORLESS MANIPULATION.** The use of motion strategies to eliminate uncertainty, without the use of sensors, is considered. The approach is demonstrated within the context of a simple method to orient planar objects. A randomly oriented object is dropped into a tray. When the tray is tilted, the object can slide into walls, along walls, and into corners, sometimes with the effect of reducing the number of possible orientations. For some objects a sequence of tilting operations exists that leaves the object's orientation completely determined. An automatic planner is described that constructs such a tilting program, using a simple model of the mechanics of sliding. The planner has been implemented, the resulting programs have been executed using a tray attached to an industrial manipulator, and sometimes the programs work. The authors explore the issue of sensorless manipulation, tray tilting in particular, within the context of a formal framework described by T. Lozano-Perez, M. T. Mason, and Rolf Taylor (1984). It is observed that sensorless motion strategies perform conditional actions using mechanical decisions in place of environmental inquiries. 12 refs.

**091198 SOLUTION ALGORITHM TO THE INVERSE KINEMATIC PROBLEM FOR REDUNDANT MANIPULATORS.** Based on a recently proposed algorithmic solution technique, the inverse kinematic problem for redundant manipulators is solved. The kinematics of the manipulator is appropriately augmented to include mentioned constraints; the result is an efficient, fast, closed-loop algorithm which only makes use of the direct kinematics of the manipulator. Simulation results illustrate the tracking performance for a given trajectory in the Cartesian space, while guaranteeing a collision-free trajectory and/or not violating a mechanical joint limit.

**091199 CLOSED-LOOP MANIPULATOR CONTROL USING QUATERNION FEEDBACK.** Euler parameters, a form of normalized quaternions, are used to model the hand-orientation errors in resolved-rate and resolved-acceleration control of manipulators. The quaternion formulation simplifies the stability analysis of the orientation error dynamics. Two types of quaternion feedback have been considered. The first type uses only the vector portion of the quaternion error, while the second is based on a Euler rotation representation. The quaternion vector approach leads to a linear feedback control law for which the global asymptotic convergence of the orientation error is readily established. The Euler rotation approach also results in asymptotic error convergence in the large except for a singularity where the hand orientation differs from its desired orientation by a rotation of  $180^\circ$ . 22 refs.

**091200 OPTIMAL ROBOT PATH PLANNING USING THE MINIMUM-TIME CRITERION.** A path planning technique is presented which produces time-optimal manipulator motions in a workspace containing obstacles. The full nonlinear equations of motion are used in conjunction with the actuator limitations to produce optimal trajectories. The Cartesian path of the manipulator is represented with B-spline polynomials, and the shape of this path is varied in a manner that minimizes the traversal time. Obstacle avoidance constraints are included in the problem through the use of distance functions. In addition to computing the optimal path, the time-optimal open-loop joint forces and corresponding joint displacements are obtained as functions of time. The examples presented show a reduction in the time required for typical motions. 19 refs.

**091201 MODELING AND CONTROL OF ROBOTIC MANIPULATORS AND MANUFACTURING PROCESSES (PRESENTED AT THE WINTER ANNUAL MEETING OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS).** This conference proceedings contains 50 papers discussing aspects related to the automation of manufacturing processes. Increased interests in automation dictates the need for better understanding of the physics involved in these processes and development of new control techniques for manufacturing automation. Modeling, feedback control and sensory information are three crucial elements in both organizing the automated factory as a whole, and in controlling unit processes. The conference papers include the following topics: Manufacturing Processes, Light metal removal with robots, Robotic manipulators, Force and compliance control, control of flexible manipulator arms, and micromechanical structures. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10833 in the Engineering Meetings (TM) database produced by Engineering Information, Inc.

**091202 DESIGN OF ROBOT MANIPULATORS BASED ON KINEMATIC ANALYSES.** Kinematic analysis represents an important tool for the functional design of robot applications. It facilitates the determination of layout arrangements for the production cell, the selection of suitable machines and equipment, the design

of task specifications and robot paths and the performance of all the tasks required by new robot manipulators. This paper describes an advanced approach for the mathematical modelling and simulation of robot kinematics and examines the following problems: 1. How to set up kinematic equations for robot manipulators. 2. How to solve the inverse kinematics for robot manipulators. 3. How to develop a simulator for robot manipulators based on kinematical models, and to incorporate it in a CAD system. (Author abstract) 25 refs.

**091204 REVAMPED ROBOTIC PROCESS CUTS SCRAP RATE BY 300%.** The Pratt & Whitney Automated Casting Facility (ACF) at Middletown, CT, billed as the only investment casting facility of its kind in the world, uses computers to monitor some 4000 operational functions simultaneously to ensure consistent high quality in the gas turbine blades it produces for F100 military aircraft engines. Robotic handling has been the only way to ensure consistent preparation of shell molds for the investment casting process. In late 1986, plant and engineering managements concluded that after more than seven years of around-the-clock duty in an abrasive dust environment, the robots were worn out and should be replaced. The replacement decision provided Pratt & Whitney the opportunity to, on the one hand, eliminate a persistent maintenance problem and, on the other hand, boost line productivity.

Nagler, Ben. *Rob Today* v 9 n 5 Oct 1987 p 25-26.

**091205 GANTRY DEMANDS FLEXIBLE CONTROL.** Flexibility plays a critical role in the cost-efficiency and application effectiveness of a robotic system. Without adequate flexibility, a manufacturer can get caught in an expensive and frustrating cycle of modifying and reprogramming systems in the field as application requirements evolve and change. Texas-based C&D Machine and Engineering Co. found a way to break that cycle through the use of the modular, microprocessor-based Motion Plus controller from MTS Systems Corporation. The Motion Plus system added the necessary flexibility and easy programmability to C&D's System II material handling robot, so that customers could program the Cartesian coordinate, three and four axis gantry-style system themselves according to their changing needs.

**091211 BASIC CONSIDERATIONS OF THE DEGREES OF FREEDOM OF MULTI-LEGGED LOCOMOTION MACHINES.** All multi-legged locomotion machines that do not need any dynamic balance control can be classified functionally into several levels. We define the minimum walking functions of multi-legged locomotion machines as follows: (i) two-dimensional walking; (ii) keeping the body horizontal on irregular terrains; (iii) keeping the absolute height of main body constant. Our main interest is in how many active degrees of freedom are necessary and sufficient to realize the above functions. The active degrees of freedom are examined in this paper using a four-legged machine which offers the minimum number of legs necessary to maintain static stability. It is shown that six active degrees of freedom are necessary and sufficient to realize the above functions. (Edited author

**091212 MODELLING ROBOT ELASTIC LINKS.** Robot elastic links are modelled as supplements. This modelling is adapted to the measuring of robot elastic features in situ. Open- and closed-loop linkages are examined. In closed-loop mechanisms, the beam-links and the rod-links are defined; the supplements modelling beam-link has three nodal points and eleven nodal values. In open-loop linkages, all the links are beam-links and are modeled as supplements with two nodal points and twelve nodal values. The rigid-body degrees of freedom are separated and the rigid-body transfer matrix is calculated. This separation leads to the displacements which represent the elastic deformation of the link, and makes it possible to calculate its flexibility matrix from the displacements measured at the nodal points. **091214 ANALYSIS OF DISCRETE DYNAMIC ROBOT MODELS.** The discrete shift-transformation matrix of general orthogonal polynomials is introduced. The discrete shift-transformation matrix is used to transform the difference equations which describe the discrete dynamic robot model into algebraic equations. Several lemmas are introduced which, together with the discrete shift-transformation matrix, solve for the joint positions and velocities of discrete dynamic robot models using discrete orthogonal polynomials approximations. The initial numerical experiment with a cylindrical coordinate robot shows the feasibility and applicability of discrete orthogonal polynomials approximations. 13 refs.

## Measurements

**091215 NON-CONTACTING, THREE DIMENSIONAL MEASUREMENT USING AN INDUSTRIAL ROBOT.** This paper describes the development and the methodology of a non-contacting, three dimensional measurement system using an industrial robot, a CCD camera together with a laser analogue sensor, and some results obtained by applying it to the measurement of objects. A frame image of an object in the working area of the robot is firstly taken by the camera mounted on the upper stand over the robot. Then its pattern, position and dimensions are recognized by a personal computer. Using these recognized data, robot operating instructions are made automatically on the computer. Successively the robot approaches the object and begins to measure the distance between it and the laser sensor according to the principle of the triangulation. By this measurement system, workpieces and houseware having fairly complicated contours can be measured precisely and reconstituted as three dimensional data in the computer memory cells. (Edited author abstract) In Japanese. 3 refs.

Medical Applications See DRUG PRODUCTS—Manufacture.

### Military Purposes

**091216 ROBOTS REACH OUT TO TOUCH NONINDUSTRIAL APPLICATIONS.** In general, the robotic systems being developed for use in these newer surroundings are more intelligent and versatile than their industrial counterparts. Mobility, for example, is a particularly important asset in many applications now being investigated, and in some situations it is a prerequisite. Nuclear installations, mining, and military reconnaissance are examples where the ability to move in an unstructured environment makes sensor-equipped mobile robots attractive. Applications of robotic equipment in the military, space stations, sentry duty, health care/human services, agriculture are described.

**091217 LONG X-TABLE UNLEASHES ROBOT.** Fixed-base manufacturing robots can inhibit a process, particularly when the product must move along a conveyor. The author describes and X-Y-Z table big enough to hold the robot, and versatile enough to follow the product - or even the operator. Two types of designs set the pattern. One, a robot table drive directly by a hydraulic cylinder. The other is a ball screw, turned with an electrohydraulic servomotor.

**091219 COLLISION-FREE TRAJECTORY PLANNING USING DISTANCE TRANSFORMS.** This paper describes a new approach to shortest collision-free path finding for robotic application. Both 2D and 3D solutions follow naturally from the development of distance transforms propagated through unoccupied space from single or multiple goal points. Steepest descent tracking from any specified starting point in unoccupied space traces out the shortest collision-free path to the nearest goal. The obstacles are 'grown to take account of the physical extent of the robotic vehicle, which itself is then represented by a reference point (initially at the start point but to be moved to the nearest goal point). Preliminary examples processed in the Computer Vision and Robotics Laboratory at the Australian National University are presented for evaluation. (Author abstract) 8 refs.

**091220 SURFACE PREDICTION AND ADAPTATION IN A ROBOT'S WORKPLACE.** Oracle is the sheep shearing robot designed and built in the Department of Mechanical Engineering at the University of Western Australia. Oracle's task is to shear the fleeced off

Merino ewes and wethers. Oracle works jointly with ARAMP, the Automated Restraint and Manipulating Platform. ARAMP is capable of holding the sheep in certain pre-defined positions, of turning it over, of registering specific points on the sheep surface, and can feed back information about global features of the surface position. This paper discusses surface prediction, adaptation and learning with reference to Oracle and ARAMP. These techniques, however, are general in nature and can be used whenever a robot is required to react intelligently with an uncertain environment. Some possible examples of intelligent robot reaction to surfaces are given. 5 refs.

**091221 NEW EFFICIENT MOTION-PLANNING ALGORITHM FOR A ROD IN TWO-DIMENSIONAL POLYGONAL SPACE.** We present here a new and efficient algorithm for planning collision-free motion of a line segment (a rod or a 'ladder') in two-dimensional space amidst polygonal obstacles. The algorithm calculates the boundary of the (three-dimensional) space of free positions of the ladder, uses this boundary for determining the existence of required motions, and plans such motions whenever possible. The algorithm runs in time  $O(K \log n) = O(n^2 \log n)$  where  $n$  is the number of obstacle corners and where  $K$  is the total number of pairs of obstacle walls or corners of distance less than or equal to the length of the ladder. The algorithm also serves as an initial demonstration of the viability of the technique it uses, which we expect to be useful in obtaining efficient motion-planning algorithms for other more complex robot systems. (Edited author abstract) 18 refs.

**091222 PATH-PLANNING STRATEGIES FOR A POINT MOBILE AUTOMATON MOVING AMIDST UNKNOWN OBSTACLES OF ARBITRARY SHAPE.** The problem of path planning for an automaton moving in a two-dimensional scene filled with unknown obstacles is considered. The automaton is presented as a point; obstacles can be of an arbitrary shape, with continuous boundaries and is of finite size; no restriction on the size of the scene is imposed. The information available to the automaton is limited to its own current coordinates and those of the target position. When the automaton hits an obstacle, this fact is detected by the automaton's 'tactile sensor.' This information is shown to be sufficient for reaching the target or concluding in finite time that the target cannot be reached. A worst-case lower bound on the length of paths generated by any algorithm operating within the framework of the accepted model is developed. Algorithms that guarantee reaching the target (if the target is reachable), and tests for target reachability are presented. (Edited author abstract) 24 refs.

Lumelsky, Vladimir J. (Yale Univ, New Haven, CT, USA); Stepanov, Alexander A. *Algorithmica (New York)* v 2 n 4 1987 p 403-430.

**091223 MOTION PLANNING WITH INERTIAL CONSTRAINTS.** A body  $B$  must move from a placement  $Z_0$  to a placement  $Z_1$  while avoiding collision with a set  $S$  of moving obstacles. The motion must satisfy an inertial constraint: the acceleration cannot exceed a given bound  $M$ . The problem is analyzed, and polynomial-time motion-planning algorithms are given for the case of a particle moving in one dimension. (Author abstract) 3 refs.

O'Dunlaing, Colm (Courant Inst of Mathematical Sciences, New York, NY, USA). *Algorithmica (New York)* v 2 n 4 1987 p 431-475.

**091224 OPTIMAL PIECEWISE LINEAR MOTION OF AN OBJECT AMONG OBSTACLES.** We present an algorithm for determining the shortest restricted path motion of a polygonal object amidst polygonal obstacles. The class of motions which are allowed can be described as follows: a designated vertex,  $P$ , of the polygonal object

traverses a piecewise linear path, whose breakpoints are restricted to the vertices of the obstacles. The distance measure being minimized is the length of the path traversed by  $P$ . Our algorithm runs in time  $O(n^4 \log n)$ . We also discuss a variation of this algorithm which minimizes any positive linear combination of length traversed by  $P$  and angular rotation of the ladder about  $P$ . This variation requires  $O(n^5)$  time. (Author abstract) 22 refs.

**091225 METHOD OF AUTONOMOUS LOCOMOTION FOR MOBILE ROBOTS.** A navigation method is presented which enables a mobile robot to perform autonomous locomotion. The feasibility of this method was demonstrated using experimental hardware - a prototype robot with ultrasonic sensors. This method uses objects of simple shape, such as poles and flat surfaces of walls selected from the environment, as landmarks and a map which indicates the relations of these landmarks. The robot moves from a given point to another along a designated path using its sensors. At each point it measures the positions of the objects selected as landmarks and corrects its path. The following basic problems encountered in realizing this method are discussed: (a) path design connecting two points in the environment; (b) the control of the robot's path; (c) measurement of the objects' positions using an ultrasonic sensor; and (d) correction of error from the designated path. (Edited author abstract) 7 refs.

**091226 DESIGN OF A ROBOT CAPABLE OF MOVING ON A VERTICAL WALL.** The development of a mobile robot which can work on the vertical walls of tall buildings, the side walls of large ships, etc. has been expected for a long time. A magnetic force or vacuum pressure is available to sustain the robot on a vertical wall, and wheels, crawlers and some other walking mechanisms can be used as the methods of moving. Many combinations of these mechanisms will be developed for various applications. Two kinds of robot model were built and tested. The air was sucked from the peripheral nozzle of the suction cup to the fan and crawlers were used as the moving system. There are two dangerous situations - slipping and falling, and their limits are determined. The aerodynamic matching between the fan and suction cup is also important to understand the safety conditions and to design an active controller to avoid dangerous situations. It is investigated using the above models. (Edited author abstract) 1 ref.

**091230 MOBILE ROBOT WITH A DEVELOPED SENSE OF SECURITY.** The Sandia Interior Robot (SIR) system was originally designed as a test instrument for evaluating various types of sensors and to help in developing robot navigation algorithms but the ultimate goal was to develop an effective mechanical sentry. Two main elements comprise the current system - the SIR mobile robot platform and a remote computer that uses navigational software developed at Sandia. The mobile platform contains an onboard central processing unit (CPU) that handles data transmission via a radio link to and from the computer, and also controls the motors and sensors on the robot. Functions performed by the personal-sized computer (PC) can be grouped into one of two categories - high-level decision-making or man/machine interfacing.

**091231 ROBUST ESTIMATOR FOR WALL FOLLOWING.** An early goal in autonomous navigation research is to build a research vehicle which can travel through office areas and factories. A simple strategy for directing the robot's movement in a hallway is to maintain a fixed distance from the wall. The problem is complicated by the fact that there are many factors in the environment, such as opened doors, pillars or other temporary objects, that can introduce 'noise' into the distance measure. To maintain a proper path with minimum interruption, the robot should have the ability to make decisions, based on measurements, and adjust its course only when it is deemed necessary. This report describes a new algorithm which enables the robot to move along and maintain a fixed distance from a reference object. The method, based on a robust estimator of the location, combines information from earlier measurements with current observations from range sensors to effectively produce an estimate of the distance between the robot and the object. A simulation study, showing the trajectories generated using this algorithm with different parameters for different environments, is presented. (Author abstract) 10 refs.

**091232 WORLD REPRESENTATION AND PATH PLANNING FOR A MOBILE ROBOT.** This paper is related to the problem of navigation of a mobile robot amidst obstacles. In order to easily take into account any modification of the environment, we propose a very simple representation of the obstacles, based on the use of

rectangles, as well as a matrix description of the spatial relationships between the obstacles. We also present a path planner based on a  $A^*$  algorithm, the features of which are specifically designed for our world of rectangles. The cost function takes into account both the length of the path and the number of turns. Some experimental results and implementation details are also given in this paper. (Author abstract) 21 refs.

**091234 COMPLEXITY OF FINE MOTION PLANNING.** This paper concerns the problem of motion planning for robots with uncertainty in sensing and control. Although this problem has been studied before, this is the first attempt at its inherent complexity. To compensate for the uncertainties in sensing and control, our robot model includes damping - a limited capacity for compliance. In this setting, we show that motion planning for point objects is PSPACE-hard by a direct reduction from polynomial-space bounded Turing machine computations. We also present a restricted version of the problem that is PSPACE-complete. (Author abstract) 6 refs.

**091235 MODEL FOR A CONTROL AND MONITORING SYSTEM FOR AN AUTONOMOUS MOBILE ROBOT.** This paper presents a model for a robot control system that is under development. The Karlsruhe autonomous mobile robot (KAMRO) will be used in a manufacturing cell, which consists of various assembly stations and a material storage system. KAMRO will be able to analyze failures and to recover in an intelligent manner. (Edited author abstract) 7 refs.

Turau, Volker (Gesellschaft fuer Mathematik und Datenverarbeitung, Darmstadt, West Ger). *Robotics* v 4 n 1 Mar 1988 p 41-47.

**091236 AUTONOME MOBILE ROBOTS.** [Autonomous Mobile Robots]. In this paper the function and structure of an autonomous mobile robot are presented. For the automatic control of such a system a knowledge based planner module, executive module and supervisor module are necessary. All modules are to be supported by a complex perception system. The functionality of such a complex device is discussed by means of the Karlsruhe autonomous mobile robot (KAMRO) developed at the University of Karlsruhe. The project is focusing on the design and the realization of a navigation module, a docking module and an assembly module. Navigation is performed with the aid of a map (map of the institute building) and sensors. Docking is controlled with the aid of tactile and visual sensors. The assembly operation sequence is generated by a planner and is executed by a hierarchy of sensors and two manipulators. Autonomy is supported by several expert systems. (Author abstract) 6 refs. **091239 ANALYSIS OF COLLISION AVOIDANCE IN MULTIROBOT CELLS USING PETRI NETS.** The analysis of cycle times in multirobot assembly cells involves the representation, specification and modelling of the cell activities. Since such activities are concurrent and asynchronous in nature, Petri nets may be used as an expedient analysis tool. The cell operations in actual cells are of a stochastic nature and involve real time control strategies. Thus analytical approaches cannot be used to analyse the resulting Petri nets. We use a generalised Petri net simulator called ROBSIM to simulate Petri net models of the multirobot cell. This paper outlines a generalised procedure for addressing the collision aspect in evaluating the cycle times using ROBSIM. We believe that the procedure can also be used for other aspects of synchronization in multirobot applications. (Author abstract). 15 Refs.

**091240 FREE RANGING AGV.** A new sensor and control structure for free-ranging operation of automated guided vehicles (AGV) has been developed and implemented. Based on the analysis of control architectures for mobile autonomous robots a control structure of Integrated Sensor Action Planning is derived. The mobile robot IPAMAR equipped with ultrasonic and optical sensors has been built for demonstration of feasibility. The vehicle navigates without landmarks. Test results of an experimental AGV course prove the control system to be robust and efficient. (Author abstract). 16 Refs.

Drunk, G. (Fraunhofer Inst for Manufacturing, West Ger). *Int J Mach Tools Manuf* v 28 n 3 1988 p 263-272.

**091241 NEW METHOD OF VEHICLE POSITION MEASUREMENT BY USE OF LASER BEAM TRACKING.** This paper describes a new method of position measurement for a vehicle travelling in two-dimensional space using laser and optical detectors. If two points set on the vehicle and a reference point form an isosceles triangle, the vehicle position relative to the reference point can be calculated by a simple relation. Then we propose a system consisting of a laser beacon at the reference point and two photo-detectors set such that they are able to rotate on the vehicle. The bearing angles of the two detectors relative to the reference point can be measured by the laser beacon. The direction of the two photo-detectors is controlled so that the difference of the two bearing angles is maximum. In order to demonstrate the above method, an experimental system is made up and used for a vehicle position measurement. The results of the

experiment show that the measurement system is effective for determining the position of the vehicle near the reference point. (Author abstract). 8 Refs.

**091242 SIGNAL PROCESSING OF A RANGE-FINDER MAP-REALIZATION SYSTEM.** This research discusses some of the basic problems of the signal processing of the range-finder, especially when it is used to reproduce a terrain map for mobile robots. The following results were obtained: (1) The reflecting points of the laser beam on the ground surface are radially distributed and, therefore, a specialized method (Radial B-spline Interpolation) can be introduced for interpolating the beam points. By separating and applying special processing methods to shadow regions, better results of the interpolation can be produced. (2) An interpolation method in association with the memorized information is shown to be feasible for signal processing of terrain. The method of memorizing terrain, and the associative application of the memory to new terrain is proven appropriate based on a computer simulation, and further improvement of the estimation is demonstrated. (Edited author abstract). 8 Refs.

**091243 STUDY OF A MAP REALIZATION SYSTEM (CANCELLATION OF AMBIENT LIGHT AND SWAYING MOTION OF A ROBOT).** For better terrain adaptability, a walking robot should be equipped with a visual sensor. This paper defines the visual sensor for a walking robot as a map realization system, abbreviated MARS, and investigates the way to realize a practical 3-D range-finder which forms the major part of a MARS. First, the improvement in the range-finder's performance to separate and extract a projected laser slit ray in ambient light is investigated. Second, structural and algorithmic considerations are made to realize real-time compensation of the swinging motion of a walking robot and to generate a terrain map while walking. As a result, it is shown that the position measurement is executed within 240  $\mu$ m per point to generate a map in real time. The experimental MARS range-finder weighs 1.8 kg and is compact. This paper shows the feasibility of producing a practical visual system for walking robots. (Edited author abstract). 9 Refs.

**091244 MANEUVERING TACTICS FOR A TRANSPORT ROBOT ON THE BASIS OF RANGE-FINDER INFORMATION. PART 2. TAKING INTO ACCOUNT THE OWN DIMENSIONS OF AN AUTONOMOUS TRANSPORT ROBOT.** Algorithms by which the motion control system of an autonomous mobile robot takes into account the dimensions of the robot body in the process of steering it around obstacles are described. Distances to the obstacles measured by a range finder and signals from sensors for close-range detection of obstacles serve as the initial data. The robot takes into account continuously the dimensions of its body and the steering features of its chassis. 8 Refs.

Gol'tsev, A.D. (Ukrainian SSR Acad of Sciences, Kiev, USSR); Kussul, E.M. *Sov J Autom Inf Sci v 20 n 4* Jul-Aug 1987 p 65-68.

**091245 PATH FINDING MOBILE ROBOT.** A path-finding mobile robot, controlled by one 8-bit microprocessor (MC 6808) and one ultrasonic sensor, has been constructed and demonstrated. All the robot (ETW-/ETS-18 HERO 1) has to do is to find a correct path according to the instruction given by an operator. A corridor in the university building is used as the experimental course. There exist several crossing points. The instruction to the mobile robot is a finite combination of

fuzzy distance, shape of the crossing point, and the direction to go ahead. The robot finds the correct way based on a fuzzy matching between the instructed fuzzy information and the observed fuzzy data. The maximum total distance from the starting point to the goal is about 1 kilometer (because of the battery limitation). (Edited author abstract). 6 Refs. In Japanese.

Hirota, Kaoru; Ariizumi, Yoshihiro. *Bull Coll Eng Hosei Univ n 24* Mar 1988 p 69-78.

**091246 MOBILE ROBOTS: REAL-TIME INTELLIGENT CONTROL.** A large system intended for military applications is described. Its architecture and associated Lisp-like plan-generation language allow the simultaneous execution of actions as diverse as road following and obstacle avoidance. The system uses off-board computation because of the quantity, size, and power requirements anticipated for the computers. A description is given of a demonstration dealing with autonomous navigation that includes path planning and execution from a map database, with concurrent obstacle detection and avoidance, over a 2-km open-terrain route at 8 km/hr by a full-sized vehicle in a natural outdoor environment. Subsequent efforts successfully achieved more rapid speeds for road following; the vehicle attained speeds of 24 km/hr and 21 km/hr on straight and curved sections, respectively, of a San Jose, California, test track. Current efforts focus on multiple-vehicle control and advanced autonomous capabilities such as dynamic re-planning, terrain typing, and landmark-based recognition. 8 refs.

**091247 POSITION VERIFICATION OF A MOBILE ROBOT USING STANDARD PATTERN.** The authors describe a system by which the critical geometric dimensions of a standard pattern are used to locate the relative position of a mobile robot with respect to the pattern. By doing so, the method does not depend on values of any intrinsic camera parameters, except the focal length. In addition, this method has the advantages of simplicity and flexibility. This standard pattern is also provided with a unique identification code, using bar codes, that enables the system to find the absolute location of the pattern. These bar codes also assist in the scanning algorithms to locate the pattern in the environment. A thorough error analysis and experimental results obtained through software simulation are presented, as well as the current direction of the work. 10 refs.

**091248 MOGRER: A VEHICLE STUDY AND REALIZATION FOR IN-PIPE INSPECTION TASKS.** A three-wheeled vehicle for in-pipe monitoring tasks is described. The vehicle moves automatically by action of a driving wheel in the direction in which the pipe extends. The relation between the stretch force and the configuration of the vehicle is analyzed to optimize the lengths of the levers and the direction in which the levers should be attached for force generation. The geometric and kinematic conditions of the vehicle for stable motion are investigated. Results of a simulation of locomotion proved the capability of self-adjustment of the vehicle to different pipe shapes and sizes. The resulting vehicle mechanism, called MOGRER, was built to carry a CCD video camera attached to its body for in-pipe monitoring tasks. Experimental results show that MOGRER can monitor while moving in an inclined pipe with a heavy angle, overcoming the effects of gravity and changes in pipe size and shape. 7 refs.

**091249 ON-LINE COMPENSATION OF MOBILE ROBOT DOCKING ERRORS.** A method to compensate for the docking inaccuracy of mobile robots is

proposed. The method is based on modifying the task of the robot arm according to the docking error, i.e., the offset between the desired and actual docking locations of the mobile robot. The docking error is sensed by a sensor mounted on the robot arm: the sensor can be either a vision system or a touch trigger probe. The algorithms for calculating the spatial docking error for each sensor and how the robot's task is modified accordingly are presented. The need for a statistical approach that will obtain results even in the presence of perturbed data is discussed and one is presented. The calculations of the spatial offset between the actual and the desired locations of the mobile robot using a vision system was implemented; results of some experiments are presented and discussed. 12 refs.

**091250 ROBOT NAVIGATION IN UNKNOWN TERRAINS USING LEARNED VISIBILITY GRAPHS - I: THE DISJOINT CONVEX OBSTACLE CASE.** The problem of navigating an autonomous mobile robot through an unexplored terrain of obstacles is discussed. Completely unexplored obstacle terrain is considered wherein the process of navigation involves both learning the information about the obstacle terrain and path planning. An algorithm is presented to navigate a robot in an unexplored terrain that is arbitrarily populated with disjoint convex polygonal obstacles in the plane. The navigation process is constituted by a number of transversals; each from an arbitrary source point to an arbitrary destination point. The proposed algorithm is proven to yield a convergent solution to each path of traversal. The visibility graph that models the obstacle terrain is incrementally constructed by integrating the information about the paths traversed so far. At any stage of learning, the partially learned terrain model is represented as a learned visibility graph, and it is updated after each traversal. It is proven that the learned visibility graph coverages to the visibility graph with probability one when the source and destination points are chosen randomly. Ultimately, the availability of the complete visibility graph enables the robot to plan globally optimal paths and also obviates the further usage of sensors. 26 refs.

**091251 PILOT LEVEL OF A HIERARCHICAL CONTROLLER FOR AN UNMANNED MOBILE ROBOT.** The controller for an intelligent mobile autonomous system (IMAS), equipped with vision and low-level sensors to cope with unknown obstacles, is modeled as a hierarchy of decision-making for planning and control. One of the levels (pilot) deals with a distorted 'windshield' view of the world and provides the actuator controller with real-time decisions. This level of IMAS controller is treated as a linguistic controller with fuzzy variables that assume values from possible intervals. The decision-making processes at this level of control are presented as a production system with a fuzzy database. The rules in the production system are derived from an analytical system model for minimum-time control. The choice of optimal motion execution commands is performed using fuzzy set operators. Also included is a temporal decision-making mechanism (reporter), which recognizes the persisting conflicts between successive levels of the hierarchy by observing the motion trajectory. 31 refs.

Isik, Can (Syracuse Univ, NY, USA); Meystel, Alexander M. *IEEE J Rob Autom v 4 n 3* Jun 1988 p 241-255.

**091252 ON TERRAIN MODEL ACQUISITION BY A POINT ROBOT AMIDST POLYHEDRAL OBSTACLES.** The authors consider the problem of terrain model acquisition by a roving point placed in an unknown terrain populated by stationary polyhedral obstacles in two/three dimensions. The motivation for this problem is that after the terrain model is completely acquired, navigation from a source point to a destination point can be achieved along

the collision-free paths. This can be done without the usage of sensors by applying the existing techniques for the find-path problem. In this communication, the point robot autonomous machine (PRAM) is used as a simplified abstract model for real-life roving robots. An algorithm is presented that enables PRAM to autonomously acquire the model of an unexplored obstacle terrain composed of an unknown number of polyhedral obstacles in two/three dimensions. In this method, PRAM undertakes a systematic exploration of the obstacle terrain with its sensor that detects all the edges and vertices visible from the present location, and builds the complete obstacle terrain model. 11 refs.

**091253 MOBILE ROBOTS.** This conference proceedings contains 39 papers. The tying together of autonomous capability with a supervising human appears to be the engineering compromise that will provide a framework for future applications of mobile robots. To be effective, the supervising human will require sophisticated interfaces with the mobile robot that allow the human to diagnose problems and teach new procedures as well as direct operations and define goals. Many of the articles address this issue from a wide variety of perspective. This volume on mobile robots provides a concise series of articles that describe current progress in path planning, obstacle avoidance, control strategies, navigation, vision systems, ranging systems, and various application of mobile robots. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11063 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**091254 LOW-LEVEL-VISION IN AN AUTONOMOUS MOBILE ROBOT.** This paper points out the sensor system of a small mobile robot (a so-called Micro Mouse), which consists of three CCD line scan cameras. The problem of the maze robot is to find the goal in the center of a maze. In contrast to the existing developments a maze robot with three CCD cameras was designed, which calculates the distance to the walls by the detection of the intensity change from the black floor to the white walls. The whole signal processing is done onboard in the small robot. This development was the base for the later construction of small laser rangefinders and a laser scanner, which is used in our autonomous mobile robot (MOBOT-III). (Edited author abstract) 2 refs.

## Modification

**091255 LOWER PRICES ATTRACT USERS TO REBUILT ROBOTS.** One sign the robotics industry is maturing is a growing sector of the market devoted to rebuilding these used industrial robots for another generation of duty. Proving again the flexibility of industrial robots, some of these models are being rebuilt for new applications. The lower cost of rebuilt robots is making it possible for more and more small companies to discover the benefits of industrial robots. The article discusses the robot rebuilding activities of six robot manufacturers.

Anderson, Larry. *Rob World* v 6 n 6 Aug 1988 5p.

**Modular** See Also WELDING, ELECTRIC ARC—Robot Applications.

**091256 DER EINSATZ VON FASERVERBUNDWERKSTOFFEN IM RAHMEN EINES ROBOTERBAUKASTENSYSTEM.** [Use of Fiber-Reinforced Composites within the Context of a Modular Robotic System].

A modular robot system permits the user to build up industrial robots of links and joint drives according to the intended kinematics. In this case, the links often determine the dynamic behaviour of the industrial robot by their mass and rigidity. The use of composite materials together with the modular structure makes it possible without the conception of a special robot to do lightweight constructions. Material-specific qualities determine the design with composite materials, which, when applied correctly, lead to considerable advantages for the users. (Author abstract). 15 Refs. In German.

## Optimization

**091257 OPTIMIERUNG DER KINEMATISCHEN ABMESSUNGEN VON HANDHABUNGSGERÄTEN.** [Optimization of the Kinematical Dimensions of Industrial Robots]. The economical use of industrial robots becomes more and more important. In this paper a computer-aided method is presented to design the kinematic structure of an industrial robot so that its workspace fits the work task in an optimal way. (Author abstract) In German. 13 refs.

Dittrich, G.; Meyer, G. *Robotersysteme* v 3 n 4 1987 p 205-208.

**091258 STANDARD CIRCULAR GAIT OF A QUADRUPED WALKING VEHICLE.** This paper introduces a more generalized gait, namely, a circular gait around an arbitrarily located turn center, and discusses a standard circular gait. The standard circular gait is the one which maximizes the speed of walking and the rotational angle in a circular walk, and this consideration forms the basis of the discussion on advanced gait control problems. This paper formalizes the problems and analyzes them by using mathematical optimization methods such as nonlinear programming. Computations are carried out on a TITAN III, the quadruped walking vehicle model constructed by the authors. Several characteristics of the optimum gait and the final gait selection chart are derived. The validity of these conditions was verified by a circular walking experiment using the TITAN III. (Edited author abstract) 8 refs.

**Performance** See Also KINEMATICS—Applications; PLASTICS PLANTS—Robot Applications.

**091259 STATIC AND DYNAMIC PERFORMANCE MEASUREMENTS OF INDUSTRIAL ROBOTS.** A static and dynamic performance test bench is presented in this paper. Static performances consist of resolution, of repeatability and of accuracy. Dynamic performances consist of comparison between three-dimensional real measured trajectories and prescribed straight line motions, together with their acceleration, joints velocities and torque or force developed by each actuator. Trajectory measurements is contactless. Torques or forces are measured by joint actuator. Influence of control system, drive mechanism, joint efficiency and link flexibility on the path accuracy of an industrial robot can be checked. (Author abstract) 1 ref.

v RA-3 n 4 Aug 1987 p 317-322.

## Personnel

**091261 SAFETY PROBLEMS RELATED TO ROBOTS.** The continuously growing rate of production and use of industrial robots has proved that, in parallel with other implementation aspects, due attention should be paid to problems related to their operational safety. Safety has to be planned and built in at the level of robot workplace. Although safety problems are encountered by various groups of personnel, it is mainly the programmer and the trouble-shooter who are at risk. There are gaps in the safety provisions which could be bridged by developing more appropriate safety equipment and by imposing minimal safety requirements upon all robots as well as by giving examples for a safety design of robot workplaces. (Edited author abstract) 6 refs.

**Programmable** See Also COMPUTER PROGRAMMING LANGUAGES; PLASTICS MACHINERY—Molding Machines; ROBOTIC ASSEMBLY—Computer Aided Design; WELDING—Robot Applications; WELDING, ELECTRIC ARC—Robot Applications.

**091263 CONCEPTUAL STRUCTURE FOR A ROBOT STATION PROGRAMMING SYSTEM.** Task level programming systems previously proposed by several authors are discussed and another approach is offered. The possibilities of integration of components such as vision and tactile modules, CAD systems, robot simulators, specialized planners, etc., are analyzed. This should help us to understand their interrelations and limitations when their integration in a system is attempted. The usual limitations of an off-line approach are analyzed and a more active role of simulation of the whole station is suggested, specially in what concerns a comprehensive sensorial simulation allowing moving to this phase most verifications, previously mandatory on the on-line phase. This should allow a more realistic plan generation, and, eventually, interactive planning with better debugging tool. In the on-line stage, emphasis is placed on the relationship between execution supervision and sensorial feedback. One suggestion of automatic plan repair, valid for any of the phases is presented. (Edited author abstract) 8 refs.

**091264 EXPERT SYSTEM FACILITATES ROBOTIC CELL PROGRAMMING.** The development and implementation of an expert system for on-line programming gets a large share of the credit for the operational and economic success of a robotic assembly cell. The cell hardware consists of a gantry robot, a Drivmatic riveting machine, end effector tooling, flexible tooling fixture, and a MV4000 cell controller. To make the cell compatible with a production environment and to increase the economic return an expert system was

developed capable of programming and managing operations of the cell. The task was to incorporate all the knowledge needed in creating a cell program into software and adding it to the existing cell control system, enhanced with knowledge about operating the cell. This knowledge came from experience gained from the original approach of off-line programming the cell, from operator manuals on the devices, and from the input of shop floor personnel involved with the original project. 2 refs.

**091266 USE OF CAD-DATA FOR THE OFF-LINE PROGRAMMING OF INDUSTRIAL ROBOTS.** Important components of IR-application programs are geometric data which are partly available from CAD-systems. The derivation and transformation of CAD-data into the required representation for IR-application programs is discussed. For the description of the geometric part of the robots task a frame concept with homogeneous coordinates is used. For the production task spot welding the determination of frames out of the geometric data from the CAD-system is shown. The use of CAD-data for simulation purposes is pointed out. (Author abstract) 7 refs.

**091269 KOLLISIONSKONTROLLE FUEHRT OFF-LINE ERSTELLTE INDUSTRIEROBOTER-PROGRAMME.** [Collision Control for Off-Line Produced Industrial Robot Programs]. An important prerequisite for cost-efficient application of industrial robots are effective programming methods. This applies primarily to new applications, and, in particular, where small batch production is involved. A step in this direction are off-line programming systems which permit program preparation in the job preparation phase. However, these systems offer at present only insufficient test possibilities, in particular with regard to a complete check of the programs for a collision-free timing of robot motions. A few first steps in this direction have been done; however, these steps are still

based on more or less specific requirements. This paper describes an approach which permits a complete check of previously designed programs by a combination of various methods and accuracy steps. Both mathematical test algorithms and the support by CAD are used for this purpose. (Edited author abstract) In German. 20 refs.

**091271 PROGRAMMING INDUSTRIAL ROBOTS FOR FLEXIBLE PALLETIZING.** This paper presents three different approaches to dealing with variations in the operations desired in a palletizing robot. The first method involves the automatic generation, compilation and downloading of the control program. Next, the use of an intelligent workcell host computer and a robot controller/host communication program are discussed. Finally, the pallet pattern generation algorithm is imbedded directly in the robot control language and an interactive dialogue is used to provide dynamic system input. While the application is specific to robot palletizing operations, the techniques discussed are appropriate for a variety of different robot tasks. (Edited author abstract) 10 refs.

**091272 LES APPORTS RESPECTIFS DES LANGAGES SYMBOLIQUES ET DE LA CAO EN PROGRAMMATION DES ROBOTS.** [Respective Contributions of Symbolic Languages and Computer Aided Design in Programming of Robots.]. A high-level robot programming language constitutes a general purpose interface for accessing the basic functional capabilities of a robot. On the other hand, CAD facilities give the possibility of using a subset of these capabilities in an easier fashion. In this paper, we show how a robot programming language and CAD facilities can be combined to obtain a robot programming system satisfying the need for generality, and allowing an easy connection with the basic robot programming functions. Such a connection is based on a 'complete' simulator providing facilities for executing robot control programs on a graphic display, for describing manipulation tasks using interactive graphic tools, for simulating the physical world and its perception through sensors, and for displaying three-dimensional scenes as shaded pictures. (Author abstract). 33 Refs. In French.

**091274 IMPLEMENTATION OF A SCHEME TO IMPROVE THE POSITIONING ACCURACY OF AN ARTICULATE ROBOT BY USING LASER DISTANCE-MEASURING INTERFEROMETRY.** The accurate positioning of an articulate robot depends on the correctness of the robot kinematic linkage mechanism. The desired or nominal linkage mechanism is never achieved, because of errors in manufacturing and assembly processes. The flexibility and backlash within the linkage mechanism are included in modeling the robot end-point position error. An auxiliary photosensing device using a beam splitter has been designed to provide 3-D robot end-point position measurement. (Edited author abstract) 7 refs.

Chao, L.M. (Univ of Maryland, College Park, MD, USA); Yang, J.C.S. *Precis Eng* v 9 n 4 Oct 1987 p 210-217.

**091275 MODEL-BASED RECOGNITION OF GLOSSY OBJECTS USING THEIR POLARIMETRIC PROPERTIES.** A model-based approach to recognition of glossy objects is presented. Normals of surface patches are obtained by analyzing the polarization state of the observed rays under illumination of light sources of circular polarization. The object is assumed to lie alone in its stable pose on the floor. Solid models are examined to find the one that matches the observed normals. First, a candidate model based on the relative angles between known surface normals is found. Then the translation so that the observed positions of surface normals coincide with those of models in the image is found. Some examples are also presented. (Author abstract) 4 refs.

**091276 MECHATRONIKAI ES ROBOTTECHNIKAI ALKALMAZHATOSAGU ELFOORDULAS ES ELMOZDULASERZEKELO ES KIERTKELO ELEMKE.** [Rotation and Displacement Sensing and Evaluating Units in Mechatronics and Robotics]. Numeric measuring systems for rotation, or displacement are used in production automation. In practice, several physical principles are suitable for this purpose, the inductive, capacitive, laser and optoelectronic solutions are the most frequent ones. The author deals with the latter in detail. According to their kinetics optoelectronic transmitters can measure straight displacement, or rotation. The code system can be absolute or incremental. Both systems have advantages and disadvantages, they are applied accordingly. The incremental system is used in practice in numerically controlled machine tools. The resolution can be directly increased using the physical optical principle, indirectly with the geometric physical principle and analog interpolation. Resolution is, in principle, limited by the division accuracy achievable, but this causes no problem in industrial applications. (Author abstract). 7 Refs. In Hungarian.

## Redundancy

**091278 ANALYTICAL TRAJECTORY OPTIMIZATION OF SEVEN DEGREES OF FREEDOM REDUNDANT ROBOTS.** The basic characteristic of kinematically redundant robots is that non-unique joint solutions may exist for a specified end effector location. Thus, trajectory planning for a kinematically redundant robot requires an optimization procedure to determine the joint displacements when solving the inverse kinematics relations. In this paper an analytical solution is developed for the trajectory optimization problem of redundant robots based on the classical Lagrange's method. A detailed formulation is provided for seven degree of freedom robots, which minimizes the Euclidean norm of joint displacements for point-to-point motion trajectory planning. (Author abstract) 7 refs.

**091283 SELECTION AND DESIGN OF AUXILIARY INDUSTRIAL ROBOTS FOR FAP.** The requirements for industrial robots (IR) operating within FAP are formulated. Methods of adaptation of robots are discussed. The ways of increasing specific hoisting capacity of IR were studied. The analysis of timely replacement of manipulatory equipment and its parts by means of unification, aggregate and module designing and respective implementation of joints was carried out. The issues of IR adaptation to the changes in configuration and dimensions of the parts to be gripped are discussed and requirements are determined for multipurpose and convertible grasping arms of IR. (Author abstract) 3 refs. In Russian.

**091284 ROBOT'S ECONOMIC REPEATABILITY.** One of the most important robot specifications in assembly is its repeatability. In the same class of robots, those with smaller repeatability range are usually more expensive to operate. In this paper a mathematical model is introduced to aid the practicing engineers in choosing the most economical robot for the considered assembly processes. The model relates the interaction between the random nature of the dimensions of the parts presented for assembly, the clearance between the mating surfaces and the robot's repeatability and its operational cost, and determines their effect on the probability of successful assembly. The results of the model are tabulated showing the acceptable clearance range of the assembled parts and the optimum robot's repeatability range for the process under consideration. 18 refs.

**091289 SENSORIZATION OF ROBOTS FOR THE ADAPTATION AND CONTROL OF AUTOMATIC ASSEMBLY.** Some problems of robot sensorization are considered. They arise in the solution of problems of component mating and of control of an automated assembly process. Sensorization is a means for analyzing situations which arise in the execution of assembly operations and altering, if necessary, the course of the operation by using spare branches in its program, which improves substantially the reliability of the assembly process. Examples of the application of a machine vision system in a visual inspection mode, and of the application of state and course of operation execution control modes by using the readings of position sensors are presented. (Author abstract) 5 refs.

**091291 HIGH-FREQUENCY ACOUSTIC SYSTEMS.** Using averaging and also temperature compensating the velocity, an air-coupled ultrasonic system operating at 500 kHz can make ranging measurements to an accuracy with  $\pm 0.004$  in. (0.010 cm) at distances up to about 10 in. (25 cm). Tests show the system resolution to

be better than 0.001 in. (0.002 cm). Averaging a number of individual readings significantly improves the accuracy of reading. By using short focal lengths and high frequency, ultrasonic beam diameters smaller than 0.050 in. (0.127 cm) can be achieved. Localized air turbulence that is not measured by the calibration transducer causes a negative shift in the reading, making the reflector appear closer than it is. The negative shift is small and should not be a problem for many applications. 1 Ref.

**091292 DYNAMIC SENSOR-BASED CONTROL OF ROBOTS WITH VISUAL FEEDBACK.** Sensor-based robot control may be viewed as a hierarchical structure with multiple observers. Actuator, feature-based, and recognition observers provide the basis for multilevel feedback control at the actuator, sensor, and world coordinate frame levels, respectively. The analysis and design of feature-based control strategies to achieve consistent dynamic performance is addressed. For vision sensors, such an image-based visual servo control is shown to provide stable and consistent dynamic control within local regimes of the recognition observer. Simulation studies of two- and three-degree-of-freedom systems show the application of an adaptive control algorithm to overcome unknown and nonlinear relations in the feature to world space mapping. 34 refs.

**091294 FORECASTING THE DIFFUSION OF INDUSTRIAL ROBOTS.** A mathematical diffusion model has been used in order to forecast industrial robots in West Germany. The calculations were done in 1985. Therefore, a comparison could be made between the forecast and the actual figures for 1985 and 1986. As the differences between forecast and actual figures are negligible the proposed model approach seems to be applicable to real world problems. It would be interesting to apply this method to other countries and other technical innovations. A main problem of the approach is data-provision. 13 refs.

**Software** See Also WELDING, ELECTRIC ARC—Robot Applications.

**091295 DISTRIBUTED CONTROL OF A ROBOT-BASED ASSEMBLY CELL.** A major problem in developing highly automated manufacturing facilities is the effort required to produce and test the complex software required to coordinate the actions of robots and vision systems and then integrate them into a manufacturing system. To address this problem, we present a distributed approach to assembly cell control where the individual sensing and manipulation systems run as separate processes in parallel under the supervision of a cell controller. The individual sensing and manipulation modules communicate with the cell controller using a

standard interface which simplifies system integration. Associated with the controller is a cell programming language that uses symbolic references to objects and features that are defined in terms of three dimensional object models. We can reprogram the assembly system to account for design changes by simply changing the object models. This will significantly reduce the incremental costs for reprogramming and retooling an assembly system to accommodate minor design changes in the components. (Author abstract) 9 refs.

**091296 REAL-TIME SOFTWARE FOR ROBOTS.** ICS. This paper describes two components of real-time software for robotics: real-time operating systems and the systems programming language. In particular, the design issues related to real-time operating systems are discussed and our own system, derived from the UNIX operating system, is described. No single real-time operating system is appropriate under all circumstances. However, it is shown that at least some continuity in the development environment can be provided. We have chosen to use a general-purpose programming language, C++, which has several advantages for real-time robot programming. In particular, it is shown how facilities within C++ can be used to guarantee initialization and proper termination of hardware subsystems. Support for concurrency is considered important, especially as robot systems become more complex. Proper support for concurrency can simplify communication and synchronization within a robot system. Two methods of providing concurrency within C++ are discussed. (Author abstract) 25 refs.

## Space Applications

**091297 USE OF COMPUTER GRAPHIC SIMULATION IN THE DEVELOPMENT OF ROBOTIC SYSTEMS.** This paper describes the use of computer graphic simulation techniques to resolve critical design and operational issues for robotic systems. Use of this technology will result in greatly improved systems and reduced development costs. The major design issues in developing effective robotic systems are discussed and the use of ROBOSIM, a NASA developed simulation tool, to address these issues is presented. Three representative simulation case studies are reviewed: off-line programming of the robotic welding development cell for the Space Shuttle Main Engine (SSME); the integration of a sensor to control the robot used for removing the Thermal Protection System (TPS) from the Solid Rocket Booster (SRB); and the development of a teleoperator/robot mechanism for the Orbital Maneuvering Vehicle (OMV). (Author abstract) 11 refs.

## Testing

**091300 OPTISCHES MESSSYSTEM ZUR GENAUIGKEITSPRUEFUNG VON INDUSTRIEROBOTERN.** [Optical Accuracy-Test-System for Industrial Robots]. This paper describes a method for the accuracy measurement of industrial robots, which is able to measure path- and position-misalignment in six degrees of freedom. Two laser beams from a laser unit with an integrated interferometer define a straight path within the working area of the robot. The tested robot moves an optical sensor head, the main component of the measurement system, along the laser beams. Analog signals from the sensor head and digital data from the interferometer are used to compute position and orientation as well as velocity and acceleration of the robot. Following a short review of the state of the art, the function of the measuring system is described in principle and an evaluation of its performance is given by some test results. (Author abstract) In German. 22 refs.

**091301 EXPERIMENTS WITH A COGNITIVE INDUSTRIAL ROBOT.** Input-expectation discrepancy reduction is a ubiquitous mechanism; it permeates the human nervous system. This mechanism thus appears to be a generic strategy underlying many aspects of intelligent behavior. The authors have applied this paradigm to the domain of industrial robotics. In addition, they have explored some applications of human perceptual mechanisms in the visual system of the robot; the general strategy employed yielded a trade-off between efficient, intelligent decisions and errors. The result is a cognitive industrial robot that exemplifies a novel view of the industrial robotics field and serves to cast some fundamental problems, of artificial intelligence (AI) as well as of robotics, in a new light. In particular, the authors describe a concrete application of their ideas which can be contrasted with most AI projects, functioning as they do in purely abstract domains. (Edited author abstract) 15 refs.

## Theory

**091302 INVERSE VELOCITY AND ACCELERATION SOLUTIONS OF SERIAL ROBOT ARM SUBASSEMBLIES USING THE CANONICAL COORDINATE SYSTEM.** The Taylor series expansion of a rigid body with three degrees of freedom is used to define and locate the canonical coordinate system for the arm subassembly of a six-axis robot with a spherical wrist. The canonical coordinate system yields the canonical form of the instantaneous kinematic equations of motion of the terminal link and the canonical form of the Jacobian matrix for the arm assembly. This form of the Jacobian matrix gives the canonical inverse velocity and acceleration solutions of the arm subassembly. As examples, the canonical inverse velocity and acceleration solutions of the spherical arm subassembly and the articulated arm subassembly are presented in the paper. A numerical example of the articulated arm subassembly is also included. (Author abstract) 23 refs.

## Vibrations

**091303 INVESTIGATION OF VIBRATIONS IN THE HAND OF AN INDUSTRIAL ROBOT EQUIPPED WITH AN IMPACT-TYPE VIBRATION DAMPER.** The problem is solved of determining the optimum parameters of an impact-type vibration damper designed to suppress vibrations in the hand of an industrial robot after it strikes the stop block. The suppression of vibrations is looked at after the hand has turned and when the column has been lowered. The effectiveness of using this type of vibration suppression in a hand is compared with that of using a dynamic vibration damper. The results are also shown of experimental investigations of the damping of vibrations caused by internal resistance. (Author abstract) 4 refs.

**091304 ECONOMY VISION.** Part manipulation by a robot is practicable provided the orientation of the presented part is known. Traditionally, a multi-part feeder will consist of either a number of dedicated feeders or else of plain feeders equipped with sophisticated electronics. The development of an inexpensive feeder with an uncomplicated recognizing device might be a good alternative. Two recognizing devices of this kind are described. One device includes a moving belt, 3 sensors and a programmable logic controller, but the device is dedicated to one particular part. The other device consists of a moving belt, 16 sensors, and a microcomputer. This device has self-learning capability. Both devices are able to offer information about the orientation of the part that will be presented to a robot. (Author abstract) 2 refs.

**091305 GENERATING OCTREE MODELS OF 3D OBJECTS FROM THEIR SILHOUETTES IN A SEQUENCE OF IMAGES.** An important computer vision task in robotics is modeling of 3D objects in a robot's workspace. This paper presents a method for generating octree models of 3D solid objects from their silhouettes obtained in a sequence of images. The silhouettes of objects which are projected into an image and the center of projection of the image generate 3D conic volumes. A 3D model of the objects is iteratively constructed by intersecting such conic volumes obtained from a sequence of images. Hierarchical octree structures are used to represent and to process 3D volume data efficiently. The volumes of individual objects are labeled by a connectivity-labeling algorithm, and surface-normal vectors are added to their surface volume elements. (Edited author abstract) 28 refs.

**091306 CAN MACHINE VISION DO THE JOB FOR YOU?** New systems and technology, combined with applications experience, are putting the benefits of machine vision within reach. But the fundamental question remains: How to measure the potential worth of machine vision in a manufacturing process? Determining whether machine vision can be applied successfully in a plant requires an evaluation of each specific application,

whether it be inspection, gauging, or robot guidance. This article reviews proven requirements for success and identifies some useful applications. Subjects covered include costs, advantages, specifying a system, and others.

**091307 THREE-DIMENSIONAL MEASUREMENTS OF TERMINALS OF LINE-LIKE OBJECTS FROM SHADOW INFORMATION.** A new vision system has been developed to measure the 3-D positions of wire terminals. Distance information of any visible point on the wires can be obtained from the images of the wires and from their shadows on a working table projected from a point light source. A theory is presented to determine the 3-D geometry of the wires from a picture taken by a television camera with prior knowledge of the arrangement of the environment, i.e. the camera, the working table and the light source. The 3-D positions of the wires can be determined from the geometry of the environment. A vertically mounted camera and a horizontal table are used in the experiments. The position error for fine wires was less than 1% of the size of sight. The principle, procedure and calculations of the measurement are described. Experimental results and discussions are presented. (Edited author abstract) 3 refs.

**091308 DESIGN OF A LARGE DEPTH OF VIEW THREE-DIMENSIONAL CAMERA FOR ROBOT VISION.** The design of a compact laser scanner for robot vision is presented. The design is based on synchronized scanners. It is shown that the Scheimpflug condition of focusing coupled with the low divergence of a laser beam provides an ideal arrangement for large depth of view. A geometrical analysis and a prototype description are presented. (Author abstract) 13 refs.

Rioux, Marc (Nat'l Research Council Canada, Ottawa, Ont); Bechthold, G.; Taylor, D.; Duggan, M. *Opt Eng* v 26 n 12 Dec 1987 p 1245-1250.

**091309 THREE-DIMENSIONAL MEASUREMENT OF MANY LINE-LIKE OBJECTS.** A method that uses two point light sources has been developed. In this method, the system operates independently of the line-like sources. Correspondences between each terminal and its shadow can then be determined uniquely. The accuracy of measurement is also improved in this new method because the position of the terminal is calculated as the intersection point of three straight lines, not two as in the previous method. Calculations of the positions of all points and orientations of all line segments are presented in this paper. Experimental results and comparisons with the previous method are also given. (Edited author abstract) 5 refs.

**091313 OCCLUSION AVOIDANCE OF VISUAL SENSORS BASED ON A HAND-EYE ACTION SIMULATOR SYSTEM: HEAVEN.** We have developed a hand-eye action simulator system called HEAVEN. This system provides model-based functions to assist the hand-eye system in visual recognition and monitoring the robot environment. This paper describes a function of assisting cameras in occlusion avoidance to input adequate image data without occlusion. The problem to select the best viewpoint for a camera is defined as to evaluate the viewpoints on a geodesic dome generated around a target object model. Occlusion-free space is obtained as regions on the geodesic dome by using a depth buffer algorithm. Then distance transformation of the occlusion-free regions gives candidates of the best occlusion-free viewpoint. Experimental results using a camera-in-hand system demonstrate the usefulness of the HEAVEN system in planning occlusion avoidance. (Author abstract) 18 refs.

**091314 SIGNAL PROCESSING OF A RANGE-FINDER MAP-REALIZATION SYSTEM.** The function to acquire three-dimensional information of the environment is crucial for the robots, especially mobile ones, and a range-finder which directly measures the range information with an active scan of a laser beam will be extensively used in the future. Based on the outlook that such range-finders will be manufactured in the near future, this research discusses some of the basic problems of the signal processing of the range-finder, especially when it is used to reproduce a terrain map for mobile robots. The following results were obtained: (1) The reflecting points of the laser beam on the ground surface are radially distributed and, therefore, a specialized method (Radial B-spline Interpolation) can be introduced for interpolating the beam points. (2) An interpolation method in association with the memorized information is shown to be feasible for signal processing of terrain. (Edited author abstract) 8 refs.

**091316 INDUSTRIAL APPLICATIONS OF COMPUTER VISION SINCE 1982.** During the past six years, the use of computer vision systems for industrial applications has become increasingly widespread. The application of vision in this context is surveyed and reviewed, according to the principal current application areas of automated visual inspection and visually guided robotic manipulation. Recently published research and development work for the identification and location of industrial components is discussed, as this forms the basis for improving the existing highly constrained application of machine vision. The survey is restricted to the period since 1982 in order to complement existing publications at or around that time. (Edited author abstract) 263 refs.

**091320 THREE-DIMENSIONAL MACHINE VISION.** In 3-D machine vision, the height (or depth or range - these three terms are used synonymously) of an object, or objects, is obtained as a function of the X and Y position. For many applications, three-dimensional machine vision may be the only viable option; for others, it is far more effective than two-dimensional. Three-dimensional machine vision systems that produce height information for an entire area of interest (usually a rectangular area) are referred to as full-field systems. An

example of data produced by a full-field system is seen in isometric plot. The focus of this article will be full-field machine vision and how to apply it. 13 refs.

**091321 IMPLEMENTING MACHINE VISION: AN IBM CASE STUDY.** This article outlines a case study by IBM of machine vision implementation in the robotic assembly area of the Automated Logistic Production System used in manufacturing computers. The ALPS process receives incoming component parts from the dock and processes these parts into completed products, packages them and prepares them for shipment, all in a totally automated environment. The major areas of the process are: receiving and parts staging, depalletizing, material distribution, robotic assembly, test, and packaging. The binary vision system integrated with the assembly robots is also described. The primary components of the hardware subsystem are a camera, interface electronics and lighting system. The software subsystem consists of AML/V and RAPID. AML/V is a high-level robot control language which has multi-tasking and image processing capabilities. RAPID is a user friendly, menu-driven program written in AML/V used for generating applications. 8 refs.

**091322 TARGET TRACKING ALGORITHM USING A SENSOR WITH BIOLOGICAL VISION FEATURES.** One of the most difficult problems in a video tracking system is the speed required for real-time operation. In this paper, a fast tracking algorithm to determine displacements of points (pixels) on object surfaces between successive frames, a sequence of image frames representing a time-varying scene, is described. The displacement is represented by a four-dimensional vector whose elements are two-dimensional translation, rotational angle on the x-y plane, and scaling factor (zoom parameter). The algorithm was developed in conjunction with research on sensors for machine vision with biological vision features. The algorithm developed is called a one-dimensional correlation algorithm and has recursive, spatio-temporal, correlation characteristics. It also possesses simplicity and separability properties. These properties make it easy to design and implement it in a highly parallel fashion. A speed comparison analysis shows that this algorithm can save 40 percent of computation time, or more, over the conventional correlation algorithm if implemented in a general purpose serial processor. Furthermore, the simulation results on a real image demonstrate that this algorithm possesses a good noise immunity property, i.e., it can be applied directly to a predefined moving area without segmentation. The properties and capabilities of the algorithm make it especially suited for robotics application with the camera mounted at the end effector. (Edited author abstract). 19 refs.

Narathong, C. (Univ of Virginia, Charlottesville, VA, USA); Inigo, R.M.; Doner, J.F.; McVey, E.S. *Int J Mach Tools Manuf* v 28 n 3 1988 p 217-233.

**091323 KNOWLEDGE-BASED VISUAL PART IDENTIFICATION AND LOCATION IN A ROBOT WORKCELL.** This paper presents a method for identifying and precisely locating parts visible in the workspace of a robot workcell through analysis of single or multiple perspective images. Automatic integration of any number of arbitrary viewpoints permits detection of objects occluded from certain views, as well as providing varying image resolution and wider coverage of the visible workspace. Analysis is possible in the presence of image noise such as glare or shadow from poor lighting conditions, or structural errors such as missing or obscured object features. Automated visual detection of camera locations avoids precise camera positioning or setup time and permits use of a movable or roving camera. The system is capable of processing multiple camera input in a few seconds on a SUN 3/160 workstation, without the use of additional image processing hardware and can be easily

ported to various computer systems. (Author abstract). 12 Refs.

**091324 NBS VISION SYSTEM IN THE AMRF.** A description is presented of the NBS Vision System. The authors discuss the objectives of the Vision System and its application in the factory environment. Since the Vision System is a multi-processor system, each process is described according to its position in the vision hierarchy as well as to its particular logical and computational functions. The interfaces between the individual processes of the Vision System and the interfaces between the Vision System and other AMRF systems are described. (Edited author abstract). 7 Refs.

**091325 MODEL-BASED 3-D VISION SYSTEM FOR BIN-PICKING.** A vision system to recognize 3-D objects in a scene and to evaluate their attitude is presented. This system uses a model-based approach to determine the attitude of 3-D industrial parts in the context of bin packing. It is based on the matching of the extended Gaussian image (EGI) extracted from the surface normal map (needle map) of an observed object with the EGI generated from a 3-D model using geometric modeling. It is shown that geometric modeling can be used to provide an object description (visible surface orientation referred to as a needle map) suited to the problem of 3-D object recognition and attitude evaluation. 17 refs.

## Wear

**091326 EFFECT OF THE NON-UNIFORMITY OF THE STRUCTURE OF FRICTION SURFACES ON THEIR WEAR RESISTANCE.** Study of the fatigue wear processes of the surfaces of parts of industrial robots under conditions of steady state wear by a method of continuous photography has revealed non-uniform separation of the products of wear from the friction surface in its various parts. It was also noticed that even in cases where the indices of dislocation saturation of the surface layer of samples after a machining operation were approximately identical, the rates of wear of the samples differed considerably from each other under the same friction conditions. This justified the assumption that the quality indices of the surface layer subjected to the machining operation have been non-uniform. To check this assumption, statistical methods were used to investigate the quality indices of the surface layer of parts. 4 Refs.

**091328 X-RAY FLUORESCENCE ANALYSIS OF SILICATE ROCKS.** Calibration curves for the analysis of 12 trace elements Zr, Sr, Rb, Th, Pb, Zn, Cu, Ni, Co, Mn, Cr and Cl in silicate rocks were obtained using the X-ray fluorescence spectrometer, JEOL JSX-60PX with eight standard rocks JB-1a, JB-2, JB-3, JGB-1, JA-1, JA-2, JG-1a, JR-1 and JR-2 provided by Geological Survey of Japan. A pressed powder method was employed for the measurement. Background, matrix and standardization corrections were carried out for the measured intensities of characteristic X-rays. The errors of analysis for JB-1a are within 5% for Sr, Ni, Mn and Cr, 5 to 10% for Zr, Zn and Rb, and more than 10% for Th, Pb, Cu, Cl and Co. (Author abstract) 11 refs. In Japanese.

## Anisotropy

**091329 EFFECTS OF ROCK LAMINATION ANISOTROPY ON DRILLING PENETRATION AND DEVIATION.** Borehole deviation is caused, in part, by the mechanical behavior of the drillstring as it buckles, causing the resultant thrust on the drill bit to deviate from the axis of the wellbore. This paper looks at some theories of anisotropic rock strength and at the possible effect of these anisotropies on the rate of penetration and hole deviation. These theories are reviewed in light of limited experimental data, and a new model is suggested to predict chip volumes and direction deviation forces based upon a combination of variable cohesive strength and single plane of weakness theories. 7 refs.

**091330 COMPRESSIVE STRENGTH CRITERION FOR ANISOTROPIC ROCK MATERIALS.** This paper proposes a general compressive strength criterion for anisotropic rock materials under multiaxial states of stress. The proposed criterion is a generalization of the Von Mises' criterion for yielding of ductile metals, which has also been used previously as a strength criterion for brittle fracture in the spirit of both being limits of linear elastic behavior. The presently proposed criterion takes into consideration the effects of the confining pressure, the various stress components, and the material anisotropy on rock material failure in a multiaxial stress state. To verify the applicability of the proposed criterion, it has been used to construct the failure envelopes for several types of rock materials. Consequently, the constructed failure envelopes and the corresponding experimental results have been compared. (Edited author abstract) 22 Refs.

## Biodegradation

**091331 BIOTRANSFORMATIONS IN MONUMENTS - A SOCIOBIOLOGICAL STUDY.** Rapid and increasing deterioration and biodeterioration of facades of stone buildings, monuments and sites has been reported in many countries and cities over the past 3000 years. Biological factors in the fields of air pollution and conservation are multiple. An integrated view of material transfer and material transport is briefly presented. Biodeterioration is defined as a socio-cultural term while biotransfer, biotransport and biodegradation describe the response of materials in contact with atmosphere, hydro-

sphere and biosphere. The processes of biotransfer and biotransport need not necessarily be regarded as biodeterioration in the context of conservation. Examples are given in which biological factors lead to momentary equilibria which are socio-culturally positive (patina). Weathering and material destruction are described in terms of the reduction of materials to less complex or different constituents. (Edited author abstract) 25 refs.

## Classification

**091334 PROPOSED GEOTECHNICAL CLASSIFICATION OF CARBONATE ROCKS BASED ON PORTUGUESE AND ALGERIAN EXAMPLES.** Carbonate rocks are common and widely dispersed materials. They include pure limestones and dolostones as well as a large variety of composites differentiated by the relative occurrence of accessory quartz, clay minerals and other components. Geotechnical properties reflect this wide variation of composition and a classification scheme would be helpful for consistent communication. References and data obtained for this study substantiated the proposed geotechnical classification based on porosity and swelling strain of the rocks. The relevance of these parameters for the explanation of the geotechnical behavior of carbonate rocks as well as their simplicity render them very suitable for this purpose. The field behavior of some Portuguese rocks is employed to demonstrate correlation with the proposed classification. (Author abstract) 6 refs.

**091335 EXPERIMENTAL STUDY OF ANISOTROPY OF STRESS CORROSION CRACKING IN ROCKS BY DOUBLE-TORSION METHOD.** A subcritical crack growth due to stress corrosion has been identified as a source of time-dependent fracture of rocks in brittle fields. The stress corrosion cracking was investigated in humid air by using the double-torsion technique for three rocks of different origin, Murata basalt, Oshima granite and Ogino tuff. The subcritical crack growth was found to be strongly dependent on the directions of crack opening and crack propagation. The maximum growth rate was higher by several orders of magnitude than the minimum one for the same rock. The anisotropy in the crack propagation was controlled by microcracks for Oshima granite and by the fabric for other rocks. (Author abstract) 39 refs. In Japanese.

Sano, Osam (Yamaguchi Univ, Ube, Jpn). *Zairyo* v 37 n 413 Feb 1988 p 152-158.

**091336 THEORETICAL STUDY OF ANISOTROPY OF STRESS CORROSION CRACKING IN ROCKS BY THE DOUBLE-TORSION METHOD.** Subcritical crack growth has a strong dependence on the directions of crack opening and crack propagation. The maximum growth rate was higher by several orders of magnitude than the minimum one for Oshima granite. From the theoretical consideration on the torsion of two thin orthotropic plates, a way for analyzing the data of the double-torsion technique for anisotropic materials was established. Based on the Christoffel's equation, nine elastic stiffness constants of Oshima granite were determined from the sound velocities,  $V_p$  and  $V_s$ , propagating in various directions. The results of the anisotropic analysis showed that the observed difference in crack velocity of different directions was not an error due to the isotropic analysis but the intrinsic nature of the granite. A theory based on the microcrack growth model showed that the difference in crack velocity by several orders of magnitude brings in a difference of only several times in dilatancy and that of only several percents in the uniaxial compressive strength. (Author abstract) 28 refs. In Japanese.

**091337 USE OF SIMULATION MODELING FOR A PROBABILISTIC ESTIMATE OF THE SPATIAL ORIENTATION OF THE DISCHARGE CHANNEL IN THE INTERELECTRODE SPACE.** The expediency of using simulation modeling on a computer for investigating the effectiveness of functioning of electrospray technological devices was substantiated qualitatively. It is shown that an algorithm for simulation modeling of the spatial orientation of discharge in the working space of the technological device should be one of the required elements of generalized algorithms for such modeling. Such an algorithm is given for the case when the spatial orientation of an individual discharge is assigned in a polar coordinate system by the relationship of the vertical and horizontal discharge angles. ## Crystalline

**091338 3-D KINEMATIC MODEL OF FABRIC DEVELOPMENT IN POLYCRYSTALLINE AGGREGATES: COMPARISONS WITH EXPERIMENTAL AND NATURAL EXAMPLES.** A 3-D generalization of the approach previously developed by Etchecopar for the

simulation of fabrics in polycrystalline aggregates is presented. The model is based on a geometric minimization of gaps, overlaps and boundary displacements between deformed neighboring cells; each cell may deform using a small number ( $<5$ ) of independent slip systems. The model is applied to experimentally flattened peridotites and sheared ice as well as to naturally sheared peridotites and quartzites. For weak deformations, the simulation matches the natural and experimental observations but, for large deformations, major discrepancies are observed; in particular the model cannot explain the obliquity of Lattice Preferred Orientation with respect to the schistosity, which is commonly observed in shear deformations. However, when taking into account a 'dynamic recrystallization' process, these discrepancies are strongly reduced and the obliquity clearly appears in simple-shear models. (Author abstract) 34 refs.

**091339 K-FELDSPAR BRECCIA FROM THE Mo-Cu STOCKWORK DEPOSIT IN THE GALWAY GRANITE, WEST OF IRELAND.** A K-feldspar breccia, spatially associated with the Mo-Cu mineralization of a stockwork in the Late Caledonian Galway Granite at Mace Head, is described for the first time. Detailed mapping reveals a network of breccia pods and veins over an area of approximately 6000 m<sup>2</sup>. The breccia is clast-supported and is composed of sub-angular fragments of perthitic K-feldspar megacrysts, granite and microgranodiorite clasts set in a matrix of quartz, biotite and apatite. Field and textural studies indicated that the feldspar megacrysts and granite clasts were brecciated and silicified as they were carried by hydrous K- and SiO<sub>2</sub>-rich fluids. The breccia formation is genetically related to ore-forming processes in the Galway Granite. (Edited author abstract). 13 Refs.

## Crystallization

**091340 PETROGENESIS AND CONDITIONS OF CRYSTALLIZATION OF SPANISH LAMPROITIC ROCKS.** The lamproitic rocks of southeast Spain (8.6-6 Ma) occur mainly as dykes and plugs in the provinces of Murcia, Almeria and Albacete. Phlogopite, olivine, apatite, spinel, sanidine and glass are ubiquitous. Clinopyroxene, orthopyroxene, K-rich amphibole, biotite, ilmenite, pseudobrookite, leucite, analcime and carbonates may be additional phases. The magmas crystallized at temperatures below ca. 1200°C. The distribution of the high-valency ( $>3$ ) elements was largely influenced by the heterogeneous distribution of accessory phases in the source and by the melt structure. The magmas were generated from an enriched mantle source containing phlogopite, orthopyroxene, olivine and accessory plates (e.g., apatite). (Edited author abstract) 48 refs.

**091341 PREDICTED AND MEASURED ROCK MASS MODULI.** Plate bearing and rock bolt jacking tests were used to measure the in situ deformational response of four jointed rock masses, namely sandstone, limestone, shale and coal. The predicted values of the rock mass moduli were evaluated using composite theory and laboratory-determined joint stiffness and intact rock moduli. Joint shear stiffness is an order that is 10 times less

than the joint normal stiffness and this has the effect of disproportionately increasing the deformational response. Good correlation is obtained when the lower values of joint stiffnesses are used in the lower bound deformational formulations. (Edited author abstract) 7 refs.

Chappell, B.A. (Bur of Mineral Resources, Canberra, Aust). *Min Sci Technol* v 6 n 1 Nov 1987 p 89-104.

**091342 DEFORMATION PHENOMENA IN JOINTED ROCK.** The role of rock joints in rock mass deformation phenomena is described. Individually, joints display concave-shaped stress-closure curves under normal loading and convex-shaped stress-displacement curves under shear, usually accompanied by dilation. The deformation behavior of rock masses depends on the relative magnitudes of these components of closure, shear and dilation. The deformation of a rock mass may result in dramatic changes in the joint apertures and conductivities. Conversely, changes in joint water pressure cause changes in joint aperture which affect the overall deformation of the rock mass. Examples of compaction in jointed reservoirs and leakage phenomena in pressure tunnels are cited, each of which may be caused by changes in effective stress. The Paper concludes by analyzing the role of joint dilation in stress transformations and in the behavior of underground openings. (Edited author abstract) 34 refs.

**091343 EN ECHELON VEIN ARRAY DEVELOPMENT IN EXTENSION AND SHEAR.** A subdivision of en echelon vein arrays is proposed, based on the geometry of sets of transcurent arrays from the Lower Carboniferous rocks in the SE midlands of Ireland. The parameters  $\delta$  (vein-zone angle) is proportional to the array orientation ( $\phi$ ) for arrays developed through secondary failure in shear zones (shear arrays). For arrays developed during propagation of an extension vein (extension arrays)  $\delta$  is proportional to the overlap of veins in the array  $P(\phi)$ . Criteria of field distinction, together with the different methods of kinematic interpretation that are required for the two types of arrays, are described. For shear arrays, the average trends of the two members of the conjugate set are calculated and the axis of principal shortening strain ( $Z$ ) bisects these. The average trend of extension arrays is parallel to that of extension veins and is therefore normal to the maximum extensional strain axis ( $X$ ). (Author abstract) 19 refs.

Rothery, Eoin. *J Struct Geol* v 10 n 1 1988 p 63-71.

**091344 SHEAR CRITERIA IN ROCKS: AN INTRODUCTORY REVIEW.** Over the last decade or so, there has been an increasing interest in the use of kinematic indicators, in other words, geological structures (often microstructures) that reveal certain aspects of the deformation history of a rock at a given scale. Amongst these are indicators of the sense or the amount of shear (or slip), in situations where the deformation history has been dominantly one of progressive simple shear (or slip). This paper discusses the subject in terms of kinematic indicators, shear zones and faults, slip system distributions, and related topics. 14 refs.

Cobbold, P.R. (Univ de Rennes, Rennes, Fr); Gapais, D. *J Struct Geol* v 9 n 5-6 1987 p 521-523.

**091345 SHEAR CRITERIA AND STRUCTURAL SYMMETRY.** During the last decade, it has been shown that most relevant shear criteria within ductile rocks are asymmetric structures (e.g. pressure shadows, shear bands, C-S structures, fabrics, tension gashes, folds, veins). The correspondence between coaxial or non-coaxial deformation, and symmetric or asymmetric particle velocity fields, respectively accounts for the use of structural symmetry as an indicator of strain history. The application of this symmetry concept to various field examples emphasizes that: (i) the degree of symmetry of a given structural pattern reflects the bulk strain regime irrespective of the size and the mechanical behavior of the considered system; and (ii) the strain regime can also be inferred from the order of appearance and dominance of

structures which contribute to the total deformation pattern, even where the progressive deformation results in a complex pattern which cannot be directly interpreted. (Author abstract) 54 refs.

Choukroune, P. (Univ de Rennes, Rennes, Fr); Gapais, D.; Merle, O. *J Struct Geol* v 9 n 5-6 1987 p 525-530.

**091346 SHEAR CRITERIA IN THE GRENVILLE PROVINCE, ONTARIO, CANADA.** The Grenville Province of Canada is a major Proterozoic orogenic belt. Mapping and structural analysis shows that the central Ontario segment of this belt is composed of a stack of imbricated thrust nappes separated by mylonite zones. The mylonite zones were generated at high metamorphic grades and contain a distinctive assemblage of mesoscopic and microscopic asymmetric structures. These structures include rotated tectonic inclusions, rotated boudins and pinch-and-swell structures, sheath folds, rotated single-crystal porphyroclasts, single crystal 'fish', and shear band foliation. The shear asymmetry indicated by these structures is highly consistent between members of the assemblage, and over a large area of the Grenville province, and shows that the thrust nappes were transported to the northwest. The consistency of the structures is thought to be due to cyclical dynamic recrystallization leading to steady-state foliations in the mylonites. (Author abstract) 40 refs.

Mawer, C.K. (Univ of New Mexico, Albuquerque, NM, USA). *J Struct Geol* v 9 n 5-6 1987 p 531-539.

**091347 KINEMATICS OF COMPRESSIONAL AND EXTENSIONAL DUCTILE SHEARING DEFORMATION IN A METAMORPHIC CORE COMPLEX OF THE NORTHEASTERN BASIN AND RANGE.** Analysis of shear criteria enables the kinematics of two main ductile-shearing events ( $D_1$  and  $D_2$ ) to be established in the Raft River, Grouse Creek and Albion 'metamorphic core complex'. The first event ( $D_1$ ) is a NNE-thrusting and corresponds to Mesozoic shortening. A well developed non-coaxial ductile deformation ( $D_2$ ), of Cenozoic age, is marked by the occurrence of opposing eastward (in Raft River) and westward shear criteria (in Albion-Grouse Creek). These characterize an arch structure where the shear strain increases outwards. In the axial zone of the complex,  $D_2$  seems coaxial. Cenozoic extension is considered to be related to gravitational instability induced by mesozoic overthickening of the crust (involving uplift, erosion and abnormal heating). Brittle extension is transformed laterally above undeformed basement towards stretched domains of the middle and lower crust through the ductile shear zones localized at the Precambrian-Paleozoic interface. (Edited author abstract) 140 refs.

Malavielle, Jacques (Lab de Geologie Structurale, Montpellier, Fr). *J Struct Geol* v 9 n 5-6 1987 p 541-554.

**091348 SHEAR STRUCTURES IN ANHYDRITE AT THE BASE OF THRUST SHEETS (ANTALYA, SOUTHERN TURKEY).** Minor-scale structures in anhydrite layers and pods within one thrust contact of the Antalya Thrust System are described. Folds whose size range from some centimeters to several meters display a wide variety of attitudes. Their axes are curvilinear and vary from orthogonal to subparallel to the stretching lineation, leading to sheath folds and eyed type sections. Shear bands are frequent. Normal and reverse fault type shear bands are self-exclusive, and both indicate a sense of shear toward the south at the scale of thrust system. A model of progressive deformation of the anhydrite layers is presented. Anhydrite layers which have undergone a strong unstable shearing deformation along a thrust have been boudinaged and now form elongate asymmetric pods. Additional aspects of the subject are discussed. 20 refs.

Marcoux, J. (Univ Paris 7, Paris, Fr); Brun, J.-P.; Burg, J.-P.; Ricou, L.E. *J Struct Geol* v 9 n 5-6 1987 p 555-561.

**091349 BULK KINEMATICS FROM SHEAR ZONE PATTERNS: SOME FIELD EXAMPLES.** This paper shows that shear zone patterns can be used to estimate both a bulk finite strain ellipsoid and aspects of the bulk deformation history. The authors describe examples of heterogeneously deformed granitic rocks which reveal the following features: (1) Shear zones show preferred orientations. (2) There are correlations between shear zone orientations and directions and senses on shear. (3) For areas that have undergone coaxial deformation histories, shear zone patterns have orthorhombic symmetries directly related to strain ellipsoid shape. (4) For areas that have undergone non-coaxial deformation histories, shear zone patterns have a lower symmetry. (5) For areas that have undergone bulk simple shear, shear senses on shear zones are consistent with the bulk shear sense. Results are compared with predictions of kinematic models involving slip along inextensible fibres and sheets. (Edited author abstract) 37 refs.

Gapais, Denis (CNRS, Rennes, Fr); Bale, Pascal; Choukroune, Pierre; Cobbold, Peter R.; Mahjoub, Yamina; Marquer, Didier. *J Struct Geol* v 9 n 5-6 1987 p 635-646.

**091350 EXAMPLE OF THREE-DIMENSIONAL ANALYSIS OF THRUST-RELATED TECTONITES.** A spaced pressure-solution cleavage related to Alpine thrusts in Mallorca (Balearic Isles) is deformed by several sets of shear planes and minor folds. All these structures formed synchronously, related to the thrust sheet movement. Shear plane sets show different orientations irrespective of the cleavage disposition. Slip along these shear planes shows that deformation did not result in plane strain. Minor fold axes show a wide range of orientations. Neither folds nor shear planes enable us to directly deduce the sense of thrust motion, indicating that these criteria must be used with care. Previous strain characterization is required for definite conclusions to be reached. (Author abstract) 35 refs.

Casas, J.M. (Univ de Barcelona, Barcelona, Spain); Sabat, F. *J Struct Geol* v 9 n 5-6 1987 p 647-657.

**091351 PRECAUTIONARY NOTE ON SHEAR BANDS AS KINEMATIC INDICATORS.** The orientation of shear bands relative to foliations defined by elongated mineral aggregates is often used to determine the large-scale sense of displacement in ductile faults. Data from contact strain zones at the bases of large overthrust complexes in the Eastern Alps and the Betic Cordilleras demonstrate that there is not always a simple geometrical relation between shear band orientation and sense of vorticity in bulk non-coaxial flow. In addition to single shear band sets that show displacements synthetic with the large-scale displacement, there are single sets with antithetic displacements, and conjugate sets. The last two observations are at variance with published data and interpretations, and cast doubts on the general applicability of shear bands as indicators of large scale flow kinematics. (Author abstract) 36 refs.

Behrmann, J.H. (Univ Giessen, Giessen, West Ger). *J Struct Geol* v 9 n 5-6 1987 p 659-666.

**091352 ROLLING STRUCTURES AT LARGE SHEAR STRAIN.** At large shear strain, shear criteria are often obliterated or become ambiguous. From examination of both natural examples and experimental models we describe a new criterion called 'rolling structure', widely represented in sheared rocks. A typical rolling structure is composed of a rigid or competent object (e.g. porphyroblast, boudin, fossil, etc.) with two tails asymmetrically disposed around it. In most cases tails are of the same material as that of the rotating object, and result from strain softening and grain-size reduction at the object periphery, forming a mantle. Z and S asymmetries of rolling structures represent dextral and sinistral senses of shearing, respectively. Tails must not be confused with pressure shadows which usually present an opposite asymmetry for a given shear sense. Besides the determination of the sense of shear, the occurrence of these structures allows a minimum estimate of the strain intensity in strongly sheared rocks, since rolling structure length is proportional to shear strain. (Author abstract) 23

**091353 PURE SHEAR AND SIMPLE SHEAR CALCITE TEXTURES. COMPARISON OF EXPERIMENTAL, THEORETICAL AND NATURAL DATA.** The authors have been investigating differences between pure shear and simple shear deformation in carbonate rocks and have found considerable agreement between textures produced in plane strain experiments and predictions based on the Taylor model. They were able to simulate the observed changes with strain history (coaxial vs non-coaxial) and the profound texture transition which occurs with increasing temperature. Two natural calcite textures were then selected and interpreted by comparing them with the experimental and theoretical results. A marble from the Santa Rosa mylonite zone in southern California displays orthorhombic pole figures with patterns consistent with low temperature deformation in pure shear. A limestone from the Tanque Verde detachment fault in Arizona has a monoclinic fabric from which it can be interpreted that 60% of the deformation occurred by simple shear. (Edited author abstract) 45 refs.

Wenk, H.-R. (Univ of California, Berkeley, CA, USA); Takeshita, T.; Bechler, E.; Erskine, B.G.; Matthies, S. *J Struct Geol* v 9 n 5-6 1987 p 731-745.

**091354 SIMPLE SHEAR EXPERIMENTS ON CALCITE ROCKS: RHEOLOGY AND MICROFABRIC.** The principal aims of this study are: (1) to compare rheological behavior and microfabric development in simple shear with earlier results obtained by coaxial testing of the same starting material; (2) to improve our understanding of the microfabric development under conditions of simple shear, both in terms of the development of grain shapes (microstructure) and the mechanisms of the development of a crystallographic preferred orientation (referred to as 'texture' in this study); and (3) to provide useful criteria for detecting rotational deformation, including information on the shear sense, for microfabric studies on naturally deformed rocks. The two calcite rocks (Solnhofen limestone and Carrara marble) were chosen because a great number of data are already available from coaxial testing of the same or similar materials, and because the flow strength of calcite is low enough to permit simple shearing with the experimental procedure chosen for this study. Many of the results are of general interest in regard to other rock-forming minerals, especially in regard to texture development under conditions of simple shear. 42 refs.

**091355 MODEL OF A PLASTIC BODY WITH INTERNAL FRICTION AND DILATANCY.** A broad class of materials (massive rock, soft soils, cast iron, composite materials, etc.) exhibit internal friction and dilatancy during deformation. At this time there exist several models of the theory of plasticity that describe these material properties together or individually. A new model of the theory of plasticity is proposed in this paper within whose framework a dependence of the dilatancy of the kind of stress state is successfully demonstrated. The computations based on the proposed model correlated well with experimental data from the deformation of mountain rock specimens. 12 refs.

**091356 'BONE-SHAPED' BOUDINS IN PROGRESSIVE SHEARING.** Some peculiar 'bone-shaped' boudins are observed in two areas of progressive shearing. They are characterized by large quartz-filled gashes that separate thinner boudins. These gashes often have a consistent obliquity, suggesting a rotation synthetic to the shear sense. These may be formed by rigid material that crystallizes in tension gashes between the boudins; during further ongoing deformation these behaved as rigid

inclusions in a more ductile matrix and show systematic rotations. The sense of rotation of the gashes constitutes a shear criterion. (Author abstract). 24 Refs.

**091357 THICKNESS-DISPLACEMENT RELATIONSHIPS FOR DEFORMATION ZONES.** Empirical relationships between thickness and displacement for different types of deformation zones in quartzofeldspathic rocks are presented. Faults exhibit a linear correlation of thickness with displacement and an average displacement/thickness ratio of 63; mylonite zones may show a similar correlation (with an average ratio of 2), though the data are problematic. The thickness-displacement relationships provide information on the growth of deformation zones with time and the role of strain softening and hardening during progressive displacement. (Author abstract). 49 Refs.

Hull, Joseph (Univ of Rochester, Rochester, NY, USA). *J Struct Geol* v 10 n 4 1988 p 431-435.

**091358 MECHANISM OF DEFORMATION AND FRACTURE IN POTASH ROCK.** Specimens of potash rock from the Rocanville mine of the Potash Corporation of Saskatchewan were subjected to uniaxial compression tests and to time-dependent creep tests under static, uniaxial loading. During the first cycle of loading, the main sources of the measured strain are compaction and dilation at grain boundaries and consolidation of the clay phase. The crystals of halite and sylvite deform elastically at low stress and in a brittle manner at high stress. There is little, if any, evidence for constant-volume plastic deformation at any level of uniaxial stress. The stress-strain curve can be divided into three parts, each representing a different dominant deformational process: a low-stress quasi-elastic, an intermediate-stress ductile, and a high-stress brittle mechanism. The deformation of potash rock is strongly time dependent. (Edited author abstract). 13 Refs.

**091359 EXPERIMENTAL STUDY OF THE ELASTICITY OF MYLONITE ROCK WITH RANDOM CRACKS.** An elastic compliance tensor for discontinuous rock masses is formulated by treating each crack with an elastic equivalent, which consists of parallel plates connected by two springs. The complex geometry of cracks, which is commonly observed in actual rock masses, is explicitly taken into account in the formulation, by means of a crack tensor. Uniaxial compression tests on eight mylonite samples were carried out to verify the utility of the elastic compliance tensor with the following conclusions: the elasticity of the samples, which have completely different appearances in terms of their crack geometry, can be compared in a general manner by the help of the crack tensor concept. Experimental results on Young's moduli of the mylonite samples are in accord with the theoretical prediction, although the strength cannot be easily related to the overall characteristics of crack geometry. (Edited author abstract) 21 refs.

**091360 INTERLAYER CONDUCTIVITY OF ROCKS - A FRACTAL MODEL OF INTERFACE IRREGULARITIES FOR CALCULATING INTERLAYER CONDUCTIVITY OF NATURAL POROUS MINERAL SYSTEMS.** A theory has been developed for

calculating interlayer conductivity for natural porous systems, such as sedimentary rocks. As the materials investigated are mainly made up of silica and alumina minerals, an electrical double layer can be presumed, which carries the physical process. A new approach has been attempted by modeling the geometrical conditions. A self-similarity model has been established for describing the porous medium, the parameters of which can be derived from physical measurements. The considerations are based on the fact that the pore wall surface is structured in all orders of magnitude in such a way that the theory of fractal dimensions is applicable. (Edited author abstract) 34 refs.

## Electric Properties

**091361 CHARACTERISTICS OF THE MULTIPLE EFFECT OF PULSED VOLTAGES ON ROCKS.** The purpose of this paper was to study the multiple effect of voltage pulses in decimeter spaces. The investigations were conducted on naturally frozen water-saturated sand (frozen ground) and alkaline granite of the Sorsk deposit. Experimental results showing the multiple-pulse strength of frozen ground and granite as a function of the number of pulses  $n$  are given as well as those of the single-pulse and multiple-pulse strength of frozen ground as a function of the length of the interelectrode space. 5 refs.

**091362 RESIDUAL WATER SATURATION, ELECTRICAL CONDUCTIVITY, AND ROUGH ROCK/PORE INTERFACES.** In this paper, we model the roughness of the pore/rock interface in terms of a random surface; we construct the surface by assigning random heights to the vertices of a triangular lattice. A completely wetting fluid preferentially lies along the concave creases of the surface and forms connected pathways that span the surface. A wetting fluid with finite contact angle does not necessarily form continuous pathways in this model. Electrical conductivity for the completely wetting case is simply proportional to the wetting-fluid saturation at very low saturations; this result agrees with recent experimental studies. (Author abstract) 11 refs.

**Energy Storage** See HEATING—Heat Storage.

## Erosion

**091365 ROCK EROSION.** This study is based on the assumptions that the rock has cracks in several directions and that water can propagate into the cracks causing pressure to build up within them. These pressure forces in the cracks act on the side and bottom of a rock block while the pressure from the flowing water acts on the top surface of the fragment. If the resulting uplift force is not balanced by the weight of the block and no other forces in the joints impede movement, the block will be lifted and carried away by the water. This paper considers the erosion of rock that is caused by water flowing parallel to its surface. This often occurs: downstream of spillways, in spillway chutes, in stilling pools and in diversion tunnels and canals. (Edited author abstract) 3 refs.

**Failure** See Also BOREHOLES—Stability; BOREHOLES—Testing; ROCK MECHANICS; SANDSTONE—Testing; SOILS—Failure.

**091366 EXPERIMENTAL METHOD TO STUDY THE DYNAMIC TENSILE FAILURE OF BRITTLE GEOLOGIC MATERIALS.** An experimental method was developed to study the tensile failure of brittle geologic materials at strain rates of approximately 10 to 20/s. In these experiments, a cylindrical rod specimen is first loaded in static triaxial compression, then the axial pressure is released from each end simultaneously and very rapidly. The resulting rarefaction waves interact in the center of the rod to produce a dynamic tensile stress equal in magnitude to the original static compression. The pressure acting on the radial surface is approximately constant during the experiment. As an application of this method, several experiments were performed on concrete. Transient measurements were made of the axial load at each end, the confining pressure, and axial and circumferential surface strains at several locations along the length of the rod. Additional aspects of the subject are discussed. (Edited author abstract) 11 refs.

**091367 SIMILARITY OF DISPLACEMENT-TIME RELATIONSHIPS BETWEEN LABORATORY AND FIELD MEASUREMENTS OF PROGRESSIVE SLOPE FAILURES.** Behavior patterns for movement of blocks with a rock slope, prior to the eventual failure, were studied using rigid physical models and employing a specially designed base-friction table with an inclinable base. Results indicate that a power law exists between elapsed time and the resultant cumulative horizontal displacement of the slope blocks, in the form of  $\log U = m \log (t/t_1)$  or  $U = (t/t_1)^m$ , where  $U$  = cumulative horizontal displacement of the slope blocks,  $t$  = elapsed time since measurement commenced,  $t_1$  = time intercept value and  $m$  = time exponent (i.e. slope of the straight line obtained). Additional results from the laboratory model studies are discussed. The influence of different slope block configurations on the behavior patterns for progressive movements of slope blocks is also discussed with respect to their resultant failure modes. (Edited author abstract) 15 refs.

**091368 CONTROL PERFORMANCE OF SERVO-CONTROLLED TESTING MACHINES.** Optimizing the control of failure process of rock under uniaxial compression testing using a linear combination of stress and strain as the control variable model analysis of servo-controlled testing machine was conducted in this study. At first stage, supposing a linear rock model, the

characteristic polynomial of the machine-rock system was obtained and examined to reduce; The control performance is influenced by the relaxation time of rock, the slope of stress-strain curve and the response time (natural frequency) of testing machine. The relaxation time is found to be a function of control speed so that the control performance is greatly influenced by the control speed. The computer simulation was conducted using a non-linear visco-elastic rock model which was recently proposed by authors. The calculated results were compared with the experimental results. It was found that the non-linear simulation model is suitable, and main results of simulation are summarized in a diagram for quick reference. (Author abstract) 9 refs. In Japanese.

**091369 BURST ENERGY RELEASE INDEX.** The rockburst is a sudden manifestation of the release of strain energy stored in the rock mass. Three possible sources for the liberated energy are: stored strain energy in the surrounding mass; change in the potential energy of the rock mass; and minor slippage along rock contacts. This paper reports on a study that focuses on the rock's capacity to store and release elastic strain energy. The purpose of this study was to search for a parameter, which represents the energy released at the time of rock fracture and which can be used as a relative measure of the burst proneness of rocks. The study was conducted on rocks from 'Sudbury Nickel Belt' in Canada. The parameter that was found, the 'Burst Energy Release Index', is described. (Author abstract). 9 refs.

**091370 KINETIC APPROACH TO THE FRACTURING OF ROCKS.** There are grounds to believe that the properties of rocks observed in quasistatic loading also characterize the behavior of rocks under dynamic loads. In this case, however, additional hypotheses have to be introduced based on an intuitive notion of the process of fracturing. Two approaches to the theory of fracturing of rocks during dynamic loading have been suggested: in one the transition of the medium from intact to fractured state occurs as a jump on the failure front (instantaneous brittle failure); in the other, the behavior of the medium during fracturing is described by a model of a hardening elastoplastic body ('gradual' failure). The present paper suggests a different approach to the description of the fracturing process. (Author abstract) 15 refs.

Glushko, A.I.; Neshcheretov, I.I. *Mech Solids* v 21 n 6 1986 p 133-139.

**091371 ON THE MODEL OF BRITTLE FRACTURE OF ROCK.** We analyze the instantaneous-fracture model with a 'force' fracture criterion in the complex stressed state under conditions of plane strain. We demonstrate that, within the confines of this model, the problem of disintegration of an arbitrary discontinuity is incorrectly posed, and therefore the model cannot be employed to solve the problem of fracture in the complex stressed state. Models of gradual fracture will not be considered. (Author abstract) 10 refs.

Glushko, A.I. *Mech Solids* v 22 n 2 1987 p 154-158.

**091372 SUBSURFACE FRACTURE SURVEYS USING A BOREHOLE TELEVISION CAMERA AND ACOUSTIC TELEVIEWER.** In the television survey, a camera probe is used to inspect the borehole walls. Measurements of location, orientation, infilling width, and aperture of fractures are made on the television screen and recorded on computer data record sheets. All observations are recorded on video cassette tapes. With the acoustic televiewer, oriented images of fractures in the borehole walls are recorded on a strip-chart log and also on video cassette tapes. The images are displayed as if the walls were split vertically along magnetic north and spread out horizontally. Measurements of fracture characteristics are made on the strip-chart log, using a digitizing table and a microcomputer, and the data recorded on floppy diskettes. Computer analysis of the fracture data, provides a rapid assessment of fracture occurrence, fracture aperture, and statistically significant concentrations of fracture orientations. **091373 FRACTOGRAPHIC DETERMINATION OF JOINT LENGTH DISTRIBUTION IN CHALK.** Measurements of fracture joint distribution combined with determination of plume length and orientation on a vertical section of a single chalk layer near Beer Sheva, Israel, reveal that joints marked by unilateral and circular plumes are skewed towards the shorter sizes while joints decorated by bilateral plumes are skewed towards the longer sizes. The mean lengths of the unilateral and bilateral joints are 66.5 cm and 155.6 cm, with standard deviations of 30 cm and 60.6 cm, respectively. These results as well as joint length observations from other areas seem to suggest a bimodal length distribution. However, since the minor maximum is generally very weak, and due to some additional uncertainties, further confirmation of the present observations is needed. (Author abstract) 18 refs.

**091374 LEACHING OF ROCK FRACTURES: LABORATORY AND FIELD TESTS FOR BOREHOLE HEAT STORES.** The aim of the project was to increase the hydraulic conductivity of fractured rock by pumping a leaching fluid (NaOH) through rock fractures. This field test was carried out in a borehole heat store, consisting of 19 vertical boreholes to a depth of 15 m in gneissic rock. The leaching process was studied simultaneously in a laboratory test where rock samples from core drillings of the test site were used. The idea of the project, that a NaOH-solution would leach and thereby widen the fractures, was not fulfilled. On the contrary the fractures were sealed as the leaching test went on. The explanation to this is that the leaching rate was higher than expected, the leaching fluid was saturated and the dissolved minerals precipitated. The results of this project has demonstrated a way of sealing rock fractures which probably has many more applications in engineering geology. (Edited author abstract)

**091375 ARTIFICIAL SUBSURFACE CRACKS AND GEOTHERMAL ENERGY.** Papers relating to artificial subsurface cracks are reviewed, with special attention given to the fracture mechanics approach to the design of the artificial subsurface heat-exchange systems used in geothermal heat extraction. This approach is compared with the classical approaches which have been employed in oil and/or gas well stimulation. A variety of methods for mapping the artificial, subsurface cracks are also reviewed since the development of the methods is one of the key themes involved in the design of subsurface cracks. The demonstrative field experiments of extracting heat from hot dry rocks are also surveyed, since they are the best practical examples. Finally, the basic concept for the design of artificial subsurface cracks is briefly de-

scribed following the successful results of the T-project at Tohoku University on geothermal heat extraction. (Author abstract) 183 refs.

**091376 DISCUSSION OF THE LENGTH LIMIT OF AN ARTIFICIAL GEOTHERMAL CRACK IN A HOT DRY ROCK ON THE BASIS OF THE TWO-DIMENSIONAL THEORY OF THERMOELASTICITY.** The theoretical analysis of propagation and closure of two-dimensional hydraulic fractures subject to the compressive tectonic stress of a linear gradient has been made by Secor and Pollard. They have found the existence of a length limit for these hydraulic fractures. In their model, however, the rock in the earth's crust is assumed to be in an isothermal state. By developing Secor and Pollard's work, the present paper is concerned with the discussion of the length limit of an artificial geothermal crack in a hot dry rock with a linear temperature gradient. The rock is assumed to be homogeneous and isotropic with respect to thermal and elastic constants. By use of the singular point method, a set of nonlinear singular integral equations is derived. The results suggest that a very artificial geothermal crack could be created in a hot dry rock with a large temperature gradient. (Author abstract) 9 refs.

**091378 SUGGESTED METHODS FOR DETERMINING THE FRACTURE TOUGHNESS OF ROCK.** Two Suggested Methods for determining the fracture toughness of rock material in the form of core specimens are described. Method 1 uses a bend specimen with a notch cut perpendicular to the core axis. The specimen rests on two support rollers and a compressive load is applied to press apart the notch sides. This causes transverse splitting of the specimen by crack growth in the ligament. Method 2 uses a specimen, called the short rod, which has a notch cut parallel to the core axis. A tensile load is applied to the specimen to pull apart the notch sides. This causes lengthwise splitting of it by crack growth in the ligament of the notched section during the test. Sampling, test apparatus, procedures, measuring equipment, and other aspects of the subject are discussed. 71 refs.

## Hydrology

**091382 METHODE HYDROCHIMIQUE POUR LOCALISER ET MESURER LES ECOULEMENTS NATURELS EN MILIEU FISSURE PEU PERMEABLE.** [Hydrochemical Method for Localizing and Measuring Natural Flows in a Fissured Medium Having Low Permeability]. The study of the variations of the chemical composition of water with depth and time in an uncased borehole in a fissured medium gives valuable information on the circulation between the borehole and the fissures it intersects. Some chemical substances may even be regarded as tracers and the rate of flow can be determined from singular points on the concentration/depth graphs at a given date. Assuming that solute transfer in the borehole column obeys an equation containing a dispersive and a convective term, the speed of forced convection in the borehole can be calculated from the series of concentration profiles, and the yields in the various fissures can be determined. This dual qualitative and quantitative aspect is examined in various types of terrain (granite, karst, orthogneiss). (Edited author abstract) 1 ref. In French.

**091383 LONG-TERM STRENGTH OF PLUTONIC ROCK.** Models have been formulated to assess the extent of microcrack extension in a rock mass, in response to mechanical or thermal perturbations. These models require slow crack-extension data in the form:  $V = AK_1^n$  where  $V$  is slow crack-extension velocity,  $A$  and  $n$  are constants and  $K_1$  is the stress intensity factor in tensile-opening mode at the microcrack tip. The purpose of this note is to record pairs of  $A$ - and  $n$ -values for several plutonic rocks from the Canadian Shield. The  $A$  and  $n$  pairs were derived from time-to-failure data of rock beams

loaded in four-point bending. The A-values were derived from the n-values and from values of critical stress intensity for the rocks in question. 7 refs.

**091384 MIDDLE JURASSIC TO EARLY CRETACEOUS IGNEOUS ROCKS ALONG EASTERN NORTH AMERICAN CONTINENTAL MARGIN.** Late Middle Jurassic and Early Cretaceous mafic dikes, sills, flows, and local volcanoclastic sediments are intercalated within continental shelf sediments from the Baltimore Canyon Trough northward to the Grand Banks of Newfoundland. The igneous rocks on the eastern North American margin are mainly alkali basalts of intraplate affinity. The major phases of igneous activity are synchronous with major regional tectonic events, namely the initiation of rifting in the Labrador-Greenland region (140 Ma), separation of continental plates between Iberia and the Grand Banks (115 Ma), and separation of Labrador and Greenland continental plates (83-92 Ma). Most of the igneous activity occurred along old fracture zones. The co-occurrence of Middle Jurassic and Early Cretaceous volcanic activity on the continental slope off Georges Bank is evidence that a hot-spot process alone cannot explain the linear character and age trends within the New England Seamounts. Propagation of a fracture zone into oceanic crust more satisfactorily accounts for the age and distribution of the volcanism. With regard to oil exploration on the continental margin, care must be taken to properly identify igneous and volcanoclastic rocks on mechanical logs, drill cuttings and cores. (Edited author abstract) 80 refs.

**091386 ELASTIC/VISCOPLASTIC CONSTITUTIVE EQUATIONS FOR ROCK.** The experimental data needed for the formulation of a constitutive equation to describe the creep of rocks in uniaxial or triaxial tests are reviewed and the influence of loading rate on dilatancy is pointed out. The assumptions which have to be made in obtaining a constitutive equation from these experimental data are specified. A general constitutive equation is then formulated for rocks, which can describe their elastic and viscoplastic properties for any triaxial compressive stress state. Dilatancy and volumetric compressibility of rocks are defined in mathematical terms and so are the concepts of the compressibility/dilatancy boundary and that of damage. Various time-dependent effects which can be modeled with such a constitutive equation are illustrated. The peculiarities of the creep phenomenon as described by the model are discussed. (Edited author abstract) 46 refs.

*Rock Mech Min Sci Geomech Abstr* v 24 n 5 Oct 1987 p 271-282.

**091387 CONSTITUTIVE MODEL AND ASSOCIATED TESTING FOR SOFT ROCK.** A general yet simplified constitutive model is proposed to characterize stress-deformation behavior of rocks. It is based on the theory of elastoplasticity and allows for factors such as hardening, volume changes, stress paths, cohesive and tensile strengths and variation of yield behavior with mean pressure. It is applied to characterize behavior of a soft rock, soapstone. The constants for the model are determined from a comprehensive series of laboratory tests under different initial confinements and stress paths by using a multiaxial testing device. The model is verified with respect to laboratory tests used for finding the constants and complex stress path tests are not used for finding the constants. (Edited author abstract) 32 refs.

Desai, C.S. (Univ of Arizona, Tucson, AZ, USA); Salami, M.R. *Int J Rock Mech Min Sci Geomech Abstr* v 24 n 5 Oct 1987 p 299-307.

**091388 FIELD METHOD FOR THE DETERMINATION OF ROCK-MASS MODULUS.** A field test for measuring rock modulus was developed and performed at the site of Darlington Generating Station in shaly limestone. The new method yields a value consistent with the rock-mass modulus evaluated from extensometer measurements in the tunnels. A complementary laboratory program to study the effect of specimen size on the elastic parameter was also performed by using compressional and shear wave velocity measurements. It was shown that beyond a threshold value of size, the Poisson's ratio increases, whereas both dynamic shear modulus and Young's modulus decrease with increasing volume of specimen towards the field value of static modulus. (Author abstract) 7 refs.

**091390 DEFORMATION AND FRACTURING BEHAVIOR OF DISCONTINUOUS ROCK MASS AND DAMAGE MECHANICS THEORY.** The mechanical behavior of a rock mass is strongly affected by discontinuities such as faults and joints. In this paper, a damage mechanics theory is proposed which deals with some sets of discontinuities distributed in a rock mass, for example, joint systems. In this theory, the distributed discontinuities are characterized by a second-order symmetric tensor, called the damage tensor. By introducing the damage concept, the deformation and fracturing behavior of the rock mass can be treated in a framework of continuum mechanics. A numerical procedure is developed in order to implement the damage mechanics model by using the finite element method. The theory and numerical analysis are applied to several laboratory tests and a practical underground opening problem. Numerical results are compared with measured data. (Author abstract) 23 refs.

**091391 EXPERIMENTAL STUDY OF STRESS WAVE TRANSMISSION AT A METALLIC-ROCK INTERFACE AND DYNAMIC TENSILE FAILURE OF SANDSTONE, LIMESTONE, AND GRANITE.** An experimental technique is described for determination

of dynamic tensile fracture strength of brittle solids. This technique has been used to determine the dynamic tensile fracture strength of several types of rock. The rocks studied were granite, limestone, and sandstone; the specimens were cored perpendicular to the bedding plane for these rocks. The quasi-static fracture strengths of the same solids were also determined for comparison with the dynamic strengths. The dynamic strengths have been found to be several times the quasi-static strengths, thus showing a strong dependence of fracture strength on strain rate. (Author abstract) 17 refs.

**091392 STRENGTH OF A REGULARLY JOINTED ROCK MASS UNDER BIAXIAL AND AXISYMMETRIC LOADING CONDITIONS.** The strength of a regularly jointed rock mass is directional. This character depends on the orientation of the joints with respect to the loading directions and the nature and anisotropy of the applied state of stress. Analytical solutions are proposed in this paper to describe the strength of a regularly jointed rock mass under the full range of states of stress that are likely to be encountered in situ with one or several stress components being tensile. The intact rock strength is described by E. Hoek and E.T. Brown criterion. The joints have no tensile strength and a shear strength described by a Coulomb criterion. Existing analytical models fail to fully take into account the influence of the intermediate stress and the orientation of the joints on the strength of a regularly jointed rock mass. The influence of these parameters is analyzed in this paper for a jointed rock mass under biaxial and axisymmetric loading conditions. 13 refs.

**091393 ESTIMATION OF THE ENVELOPE OF MAXIMUM MOHR'S CIRCLES PREPARING THE STRENGTH TEST CERTIFICATE OF ROCKS.** Strength test certificates are the principal documents characterizing the strength properties of rocks. Essentially, these are reports of experimental tests of a specific strength theory. In estimating the strength of rocks, Mohr's theory and its modification are commonly used. There is a large number of equations for the envelopes of the maximum Mohr's circles derived mostly from experimental data by fitting of a curve (which is usually algebraic). The requirements for the envelopes are specified. Some of the envelopes covered include Coulomb-Mohr envelope, Ruppenet's envelope, and parabolic envelopes. 18 refs.

**091394 ARCuate HINGE CLEAVAGE ASSOCIATED WITH WELDED CONTACTS: AN EXAMPLE.** Arcuate hinge cleavage (a.h.c.) shows a near bedding-parallel, concentric, arcuate development within the inner arcs of hinge zones. It is favored by alternating layers of marked viscosity contrasts with little layer-parallel shortening prior to parallel folding. A field example of a.h.c. from a greywacke/pelite sequence of the Variscan of Central Europe is presented. The a.h.c. is developed as a slaty cleavage in the inner-arc hinge zone of pelite beds close to and welded to the outer arc of greywacke layers. Microscopically it is defined by the alignment of platy minerals and oblate quartz grains. The a.h.c. ( $S_2$ ) is cut by a divergently fanning crenulation cleavage ( $S_3$ ) which, in turn, is cut by slip surfaces parallel to bedding. The slip surfaces are cut by a fracture cleavage which is the macroscopically observed axial surface cleavage ( $S_4$ ). This sequence of deformational increments implies the onset of

bedding slip after the formation of a.h.c. ( $S_2$  and  $S_3$ ). We therefore suspect inhibited bedding slip by welded contacts to favor the development of a.h.c. (Author abstract) 21 refs.

**091395 DEFORMATION VOLUME AND CLEAVAGE DEVELOPMENT IN METASEDIMENTARY ROCKS FROM THE BALLARAT SLATE-BELT.** Pssammites from the Ballarat slate belt in SE Australia exhibit well-developed differentiated or spaced cleavage defined by alternating phyllosilicate- and quartz-rich domains (termed P- and Q-domains, respectively). Strain estimates derived from independent microstructural and chemical observations suggest that the P-Q fabrics developed in response to plane-strain deformation dominated by solution transfer with the principle finite shortening in the P-domains approximately twice that in the adjacent Q-domains. Significant finite extensions are indicated by ubiquitous quartz-albite-chlorite overgrowths in both P- and Q-domains, while pressure-shadow development around syntectonic pyrite porphyroblasts suggest finite extension of at least 100%. This estimate is comparable with the extension predicted for constant-volume deformation and consequently there appears to have been no significant bulk materials loss or gain on the hand-specimen scale. Additional aspect of the subject are discussed. (Edited author abstract) 40 refs.

**091396 SHEAR CRITERIA IN GRANITE AND MIGMATITE DEFORMED IN THE MAGMATIC AND SOLID STATES.** This study is a by-product of the detailed structural and microstructural investigation of a high-grade metamorphic rock pile (Variscan Vosges Massif, France) which underwent subhorizontal shearing during partial melting and further solidification. Depending on the rock chemistry, on the position in the pile and the relative timing of progressive deformation, layered migmatites and homogeneous granites were variously deformed in the partially melted and solid states. The sense of shear obtained from these rock types, using the criteria presented here, consistently gives a top to SW direction. (Edited author abstract) 37 refs.

**091397 ANTITAXIAL CRACK-SEAL VEIN MICROSTRUCTURES AND THEIR RELATIONSHIP TO DISPLACEMENT PATHS.** The microstructures developed in an example of a syntectonic crack-seal vein indicate that antitaxial fibers do not necessarily track the incremental opening history during crack-seal vein growth. This observation serves as a caution against the uncritical use of fibrous microstructures to make inferences about displacement histories during fiber formation. It is demonstrated that crack-seal processes can lead to the development of both irregular and laminated vein microstructures, as well as fibrous microstructures. The types of microstructures which develop in crack-seal veins, and the extent to which they reflect the opening paths of veins depend on a range of factors. The most important of these include the nucleation and growth kinetics of phases precipitated from fluids in opening fractures, and the location of sites of material accretion during successive crack-seal increments. **091398 PREFERRED ORIENTATION OF PHYLLOSILICATES IN PHYLLOMITES AND ULTRAMylonites.** X-ray texture goniometry operated in the transmission mode has been applied to fine-grained,

phyllosilicate-rich SC-mylonites. Basal planes (001) phyllosilicate pole-figures depart in two respects from orthorhombic symmetry. Optical microscopy reveals S- and C-surfaces and sets of shear bands (SB) characteristic of non-coaxial deformation. The pole figures are used for two purposes. (a) The first is strain estimation after the March model by imposing orthorhombic symmetry. The resulting March strains are more or less the same in all Californian samples. This is interpreted as evidence for a 'steady state foliation'. (b) The second is shear sense determination. It is demonstrated that consistently asymmetric preferred orientations reflect structures which are typical of non-coaxial deformation. Study conclusions are discussed. **091399 TIME AND FREQUENCY RESPONSE OF TRACER EXPERIMENTS.** Two distinctly different approaches to the interpretation of advective and dispersive transport characteristics of an intermediate scale (0-6 m) tracer experiment are examined and compared. The first, or time domain method, is based on a direct analysis of the tracer breakthrough via the widely used moment method. The second, or frequency domain method, is based on a comparison of the Fourier transform of the tracer breakthrough and its theoretical counterpart, the frequency response function. Both methods provide satisfactory estimates of the mean advective transport component of the experiment for both conservative and nonconservative tracers. For the sampling ports closest to the source (0-2 m), the moment method produces much larger estimates of the dispersivity than the frequency response method. This difference is attributed to a buildup of errors in the estimation of higher moments, resulting from local variations in the tracer and fluid migration rates within this zone. The frequency domain approach is less sensitive to random variations in the breakthrough response. This idea is illustrated with an example from optimal filtering theory. (Edited author abstract) 15 refs.

**091400 FIELD STUDY OF SEEPAGE AND MIGRATION PROCESSES IN FISSURED-POROUS ROCKS.** Problems of parametric substantiation of seepage and migration (mass transfer) models for heterogeneous fissured-porous rocks are considered. Principles of diagnosing the experimental curves of pumping tests are discussed and the role of factors distorting the results of their interpretation within the framework of simplified asymptotic schemes is assessed. Emphasis is placed upon the possibility of manifestation of nonlinear effects and on the specific features characterizing propagation of a hydrodynamic wave in semipervious clay strata with heterogeneous storage capacity and permeability. Practical recommendations for planning and interpreting tracer tests are given. The substantiation of tests is shown to require, in particular, exclusion of hydrochemical lag in hydrodispersion in fissures and the influence of regional flow. Since only a limited number of migration parameters can be studied by means of such tests, specialized regime observations are proposed as an alternative approach. (Edited author abstract) 12 refs.

**091401 EXPERIMENTAL MEASUREMENTS OF THE DIFFUSION PARAMETERS OF LIGHT HYDROCARBONS IN WATER-SATURATED SEDIMENTARY ROCKS - II. RESULTS AND GEOCHEMICAL SIGNIFICANCE.** Diffusion parameters (diffusion coefficient, diffusion permeability, solubility coefficient) for methane, ethane, propane, n-butane, me-

thylpropane and 2,2-dimethylpropane were measured on 21 samples of water-saturated sedimentary rocks at different temperatures (30, 50, and 70°C). The rock samples include sandstones, siltstones, and claystones with porosities ranging from 0.4 to 16.5 percent and permeabilities from < 0.005 to 33.4 millidarcy. Diffusion coefficients decrease with increasing molecular weight of the hydrocarbon compound, the decrease depending on the petrophysical properties and the mineralogy of the rocks and being most drastic in shales. None of the petrophysical parameters examined in this study (porosity, permeability, formation resistivity factor) gave a good correlation with the nonsteady-state diffusion coefficient, D. An excellent correlation was found between the formation resistivity factor, F, and the steady-state diffusion permeability, P. A possibly useful - though less significant - relation bearing some resemblance with Archie's law appears to exist between the porosity and the diffusion permeability. (Edited author abstract) 35 Refs.

**091402 USE OF PERMEABILITY AS AN INDEX TO CHARACTERIZE INTERNAL STRUCTURAL CHANGES AND FRACTURE MECHANISM.** This study investigated the possibility of using variation in the permeability as an index to characterize internal structural changes and fracture mechanism of a soft rock under triaxial loadings. Extensive triaxial tests were carried out on soft rock specimens to examine this idea. These tests include (1) triaxial compression tests with low and high confining pressures, (2) triaxial tests with relaxations, and (3) cyclic triaxial tests. The results of the study confirm that observation of change in the permeability provides an excellent way of characterizing the internal structural changes and fracture mechanism of the soft rock under triaxial loadings. (Author abstract) 8 refs.

**Phase Diagrams**

**091403 GEO-CALC: SOFTWARE PACKAGE FOR CALCULATION AND DISPLAY OF PRESSURE-TEMPERATURE-COMPOSITION PHASE DIAGRAMS USING AN IBM OR COMPATIBLE PERSONAL COMPUTER.** Geo-Calc's general program flow consists of calculation of reaction coefficients among phases in the selected chemical systems, computation of the equilibrium position for each reaction curve whereas each point on the curve is tested for metastability against all other phases, elimination of metastable extensions and of reactions that involve metastable assemblages, and plotting of all resulting curves with labels identifying the stable assemblages. Other programs in the Geo-Calc package display the phase diagram on the screen (CGA, EGA, or HERCULES graphics adapters), print it on an Epson or compatible dot-matrix printer at the resolution of the printer and improve diagram legibility by moving the labels or replacing them automatically with numbers so reaction identifiers do not overlap. Geo-Calc is distributed with a recommended thermodynamic database, but a variety of equations of state are provided so that the programs can be used with different data sets. Run time options include selecting the type of diagram, selecting the chemical system, setting the P-T-X limits of the diagram, selecting ideal or nonideal H<sub>2</sub>O-CO<sub>2</sub> mixing and specifying whether phases are to be projected from, included in all reactions, or have a fixed activity other than unity. **091404 SYNTHESIS OF HYDRAULIC PROPERTIES OF ROCKS WITH REFERENCE TO THE BASIN AND RANGE PROVINCE, SOUTHWESTERN UNITED STATES.** Hydraulic properties of rock types common in the Basin and Range province were synthesized. For material that is granular and well sorted consisting of particles of approximately the same size and uniformly packed, the intrinsic permeability is a function of the square of the median grain size. For granular well-sorted material with a broad range of grain sizes and argillaceous material, permeability may be an exponential function of the porosity. For fracture unweathered crystalline rock, the permeability is an exponential function of the porosity if the fracture density and geometry is uniform. Beneath the zone of weathering, the average bulk-rock intrinsic permeability decreases as depth increases, owing to overburden pressure. The most permeable rocks include fractured karstic carbonate rocks that have hydraulic-conductivity values ranging from  $10^{-1}$  to  $10^5$  meters per day, coarse-grained basin fill that has hydraulic conductivities from  $10^{-1}$  to  $10^3$  meters per day, and fractured basalt that has hydraulic-conductivity values as great as  $10^3$  meters per day. Additional study results are discussed. (Edited author abstract) 60 refs.

## Pore Pressure

**091406 EFFECT OF PORE PRESSURE ON THE CYCLIC FATIGUE CHARACTERISTICS OF WATER SATURATED ROCKS UNDER CONFINING PRESSURE.** In order to clarify the effect of pore pressure on cyclic fatigue characteristics of water saturated rocks under confining pressure, cyclic fatigue tests using 1 Hz sinusoidal wave of pulsating compressive stress were carried out under both confining pressure and pore pressure for Kimachi sandstone and Hirono sandy mudstone laying emphasis on endurance limit and the change of volumetric strain in cyclic fatigue process. Under the condition of constant pore pressure and constant confining pressure, endurance limit exists for both rocks. Pore pressure remarkably decreases both number of cycles to failure and endurance limit. Stress ratio corresponding to endurance limit increases with b value in equation (1), which means that the lower the stress ratio corresponding to endurance limit is, the more number of cycles is required to reach the endurance limit. Pore pressure promotes dilatancy in fatigue process of water saturated rocks, and lowers endurance limit and the number of cycles to failure. (Author abstract) 4 refs. In Japanese.

**091407 PORE-THROAT SIZE CORRELATION FROM CAPILLARY PRESSURE CURVES.** Void spaces in porous media can be considered as three-dimensional networks consisting of bulges (pores) connected by constriction (throats). Computer simulations of drainage-imbibition processes show that the critical end points of wetting-phase and nonwetting-phase saturation, in drainage and imbibition respectively, and the form of simulated relative permeability curves all were significantly different for uncorrelated and correlated pore-throat models. Since these models were identical except for the arrangement of throats in relation to pores, the degree of pore-throat size correlation appears to be an important property influencing flow and fluid displacement. Examples of uncorrelated and correlated pore-throat structures in rocks are presented and it is shown that this property, although difficult to quantify by direct observation, can be evaluated from capillary pressure curves. (Author abstract) 19 refs.

Wardlaw, N.C. (Univ of Calgary, Calgary, Alberta, Can); Li, Y.; Forbes, D. *Transp Porous Media* v 2 n 6 Dec 1987 p 597-614.

**091408 SCALE EFFECT ON ROCK FISSURATION POROSITY.** The scale effect on rock fissuration porosity is analyzed by means of a structural conceptual schematic diagram designed for a reservoir of cubical blocks separated by clefts with constant openings. Two cases are considered: (1) either the blocks are compact (simple porosity due to clefts) or (2) the blocks are affected by fissuration porosity (in which case the system has double fissural porosity). This hexahedral schematization is consistent with what is often noted in tectonic fissuration. Porosities are calculated for increasing volumes whether they be spherical or cubic, and these porosities are expressed in relation to the average effective porosity of the aggregate. Representative porosities can probably be reached only for volumes in excess of  $10^6 \text{ m}^3$ , even in the best circumstances. (This is the representative elementary volume). For such volumes, an experimental approach seems difficult. The author concludes that research into this type of porosity should be carried out by statistical methods. 26 refs.

**091409 STUDY ON THE ANALYSIS OF GROUND WITH DOUBLE POROSITY MODEL.** An idealized double porosity model is developed for the purpose of studying the coupled-effects of flow in porous blocks and fractures as well as solid displacement in saturated-unsaturated medium. Subsequently, Galerkin formulation is used for the finite element method to develop a new technique to investigate coupled hydraulic-mechanical behavior in the double porosity model reservoir. The verifications are performed in comparison with an analytical solution of one-dimensional consolidation problem and experimental results of unsteady flow in the sand box. Finally, a secondary compression is examined with this model, the environment of rock mass in Lugeon test is simulated, and two-dimensional consolidation problems in a saturated and saturated-unsaturated media are investigated with comparison with the single porosity model. (Author abstract). 19 Refs. In Japanese.

## Pressure Effects

**091410 COMPUTER MODELS OF PRESSURE SHADOWS: A METHOD FOR STRAIN MEASUREMENT AND SHEAR-SENSE DETERMINATION.** In this paper a computer model of pressure-shadow growth is presented based on a principle of geometrical best fit between a rigid object and a deformable matrix. By

varying the parameters in the simulation, pressure shadows of different shapes can be generated and matched by trial-and-error with specific natural examples. Thus the method is able to give estimates of crystallization laws, finite strain and deformation path. Simulations carried out for a number of natural examples show that: (1) the pressure-shadow infilling material can be rigid or deformable and the direction of growth appears to be mostly 'displacement controlled'; (2) the finite strain is larger than what appears from the shape of the pressure shadow; and (3) the deformation path may be 'replayed' by the simulation. From the results of the simulations we emphasize the morphological characteristics of pressure-shadows which can be reliably used for shear-sense determination. (Author abstract) 38 refs.

**091414 MICROGEOMETRY AND TRANSPORT PROPERTIES OF SEDIMENTARY ROCK.** This monograph describes recent progress in modelling the transport properties of sedimentary rock. Statistical descriptions are applied to the pore-space geometry and to the transport processes involving pore fluids. Fractals are used to quantify the pore geometry at length scales shorter than grain size. Percolation theory is applied to fluid flow. The permeability can be expressed in terms of a single effective pore diameter measured from mercury injection capillary pressure. This permeability relation is valid for essentially all porous rock and for a broad class of porous media. Mercury injection provides a powerful caliper of the geometry of a percolation cluster in a pore-space and supplies new information about pore space correlations and dynamics of fluid displacements. The statistical description of fluid transport in porous media has analogues in disordered electronic and magnetic materials. Future work may make substantial use of such analogues to solve more complex problems of direct relevance to petroleum exploration and production. (Author abstract) 150 refs.

**091416 SWELLING BEHAVIOUR OF PELITIC ROCKS - EXPERIMENTAL INVESTIGATIONS FOR ASSESSING THE INFLUENCE OF MINERALOGICAL AND SEDIMENTOLOGICAL FACTORS.** Numerous swelling-pressure measurements have been carried out on pelitic rocks of different composition over the past years. Mineralogical composition, grain size distribution and Atterberg values were established simultaneously. The results obtained indicated varying degrees of interdependence. It was noticed that specific mineralogical and geotechnical factors could be correlated in different ways with the swelling pressure established. The time element in the formation of expansion stresses also reflected previous loads to which the rock had been subjected in its geological past. Artificially produced rock cubes made of homogenized sample material were investigated too in order to permit the determination of swelling pressure with sediments not suitable for the production of standard cubes. The expansion stresses obtained by this method were all low ones. Study results are discussed. (Edited author abstract) 20 refs.

**091417 SEDIMENTARY PHOSPHATE ROCK IN ALBERTA AND SOUTHEASTERN BRITISH COLUMBIA: RESOURCE POTENTIAL, THE INDUSTRY, TECHNOLOGY AND RESEARCH NEEDS.** Approximately 2.0 million tonnes of phosphate rock is imported from the U.S. to Alberta annually and is used in the production of agricultural fertilizers. No phosphate rock is presently mined in Canada, although sources of

igneous phosphate have been mined in the past. Sedimentary phosphate rock is found in nine geological units within the Cordilleran Foothills and Front Ranges region of Alberta. The Devonian-Mississippian Exshaw Formation, Permo-Pennsylvanian Rocky Mountain Supergroup, and the Jurassic Fernie Formation have the best potential for future development. Most of the phosphate rock in Alberta is of low grade and lies within restricted land use areas. The best over-all resource potential lies in the Fernie basin area of southeastern British Columbia, in the Fernie Formation. The possibility of deep phosphate rock deposits in the plains region should be examined. U.S. supplies of phosphate rock are secure until the year 2000; however, by this time, the richer deposits in the U.S. may be exhausted. Alternate deposits, such as the ones in Alberta and British Columbia, might then be considered. (Edited author abstract)

**091419 GEOCHEMISTRY OF MAIN STRUCTURAL BONDS BETWEEN MINERALS IN ARGILLACEOUS ROCKS OF THE LOWER CRETACEOUS.** Pelitic sediments of the Lower Cretaceous in northwest Germany with a wide spread range in the contents of various clay minerals and carbonates were tested by using water and certain solutions. The aim was to investigate the kind and stability of the main structural bonds between minerals. Common investigations show the physicochemical properties of rocks to depend mainly on their grain size distribution, their mineralogical composition, texture and microtexture, their contents of finely dispersed humic material and their natural water contents. More detailed investigations carried out here proved that also other parameters are necessary to describe the geochemistry of the structural bonds in a better way. The stability of clayey to marly rocks against the disaggregation by water and certain solutions depends mainly on the total cation exchange capacity. Additional study results are discussed. 8 refs.

**091420 CHARACTERISTICS AND ORIGIN OF FRACTURE-HOSTED IMPSONITE, QUEBEC CITY AREA, CANADA.** Allochthonous Cambro-Ordovician sedimentary strata from the Quebec City area contain fracture-coatings and fracture-fillings of solid organic matter, ranging up to several centimeters in thickness. This material was apparently emplaced epigenetically as a viscous fluid but now occurs as soft, black solid having a brittle, conchoidal fracture. Small euhedral quartz crystals, generally less than 10 mm in length, occur in open fractures throughout the study area and commonly contain angular solid inclusions of impsonite. Doubly terminated crystals have been found completely encased in impsonite, suggesting that both materials formed simultaneously. The evidence suggests that the fracture-filling impsonite is the solid residue of a petroleum mixture that was at one time comprised of a number of immiscible phases, including at least two aromatic-rich liquids, a gas or supercritical vapor, tiny dispersed fragments of proto-impsonite, various other solid organic phases, and an aqueous phase containing dissolved silica. Crystallines of impsonite agglomerated to form a coherent mass, with

concomitant loss of the fluid phases. 4 refs.

**091421 THERMOGRAVIMETRIC FOURIER TRANSFORM INFRARED SPECTROSCOPY (TG-FTIR) OF PETROLEUM SOURCE ROCKS. INITIAL RESULTS.** The first results of thermogravimetric Fourier transform infrared analysis (TG-FTIR), as applied to petroleum source rocks, are reported. Sample preparation and running time, roughly equivalent to those used for Rock Eval source rock pyrolysis analyses, are described. Initial results show that the TG-FTIR technique provides considerable additional geochemical information including the following: (a) Simultaneous T<sub>max</sub> values for thermal evolution of a number of constituents are obtained. (b) Data required for calculation of material balances of organic and inorganic sedimentary carbon, nitrogen, and sulfur are obtained. (c) Data for classification of sedimentary organic matter into kerogen types I, II, and III as well as data for classification according to depositional environment are obtained. (Edited author abstract) 28 refs.

**091422 APPLICATION OF THE DISTINCT ELEMENT METHOD FOR ANALYSIS OF TOPPLING OBSERVED ON A FISSURED ROCK SLOPE.** The Distinct Element Method (DEM) is one of the most suitable analytical methods for examining the stability of fissured rock slopes which are separated into many blocks with open joints. Although P.A. Cundall et al., G. Hocking and M.D. Voegele suggested with the results of their numerical analyses that DEM can be applied to the analysis of toppling of fissured rock slopes, the application of DEM to an actual case has not yet been reported. In this note, the authors describe observed toppling of a fissured rock slope and compare this to the results of DEM analysis on the phenomenon. 9 refs.

**091424 STABILIZATION WITH ROCK ANCHORS OF TWO CUTTINGS ON NATIONAL ROUTE N13.** During the construction of a section of National Route N13 (Johannesburg Southern Bypass) two large cuttings were excavated. The first, in andesite lava, was adjacent to a Rand Water Board pipeline and the second, in quartzites, adjoined private dwellings. The cuttings were restrained with stressed anchors and unstressed dowels and the exposed faces were protected by concrete panels. The geotechnical design of the lateral support in the andesite was problematic, owing to the

unpredictable variations in rock weathering. By contrast, the quartzite cutting was uniformly weathered, with consistent patterns of jointing, and design problems were concerned mainly with the overlying transported soil. (Author abstract) 4 refs.

**091425  $R_p/\phi_p$  STRAIN ANALYSIS USING AN ORIENTATION NET.** Since the classical work of E. Cloos, deformed distributions of elliptical objects such as ooids or pebbles have been recognized as an extremely important category of geological strain marker. However, elliptical objects are not easily analyzed, especially where primary sedimentary fabrics are tectonically imbricated. This paper demonstrates that previously published analytical techniques generally address only specific aspects of deformed ellipse distributions; as research tools, they are like a stereonet with great circles only or small circles only. All of the above methods can be combined with the aid of a new orientation net which is as convenient to use in the field as a standard stereonet. Uniform and imbricate fabrics are evaluated with equal ease and assumptions are subjected to statistical testing. (Author abstract). 59 Refs.

**091426 STRAIN ANALYSIS IN ROCKS WITH PRETECTONIC FABRICS: DISCUSSION.** J. Wheeler presents an algebraic solution to the determination of strain in rocks with a pre-tectonic fabric. The discussion authors feel that Wheeler's contribution could be clarified by some further observations. Their purpose is to illustrate the problem plaguing two- vs three-dimensional fabric data. To do this, the analysis goes back to the basic assumptions behind fabric analysis to study deformation paths, pebble fabrics, envelope surfaces, and other aspects of the subject.

De Paor, D.G. (Johns Hopkins Univ, Baltimore, MD, USA); Kusky, T.M. *J Struct Geol* v 10 n 5 1988 p 529-530.

**091427 STRAIN ANALYSIS IN ROCKS WITH PRETECTONIC FABRICS: REPLY.** The reply addresses the comments of D.G. De Paor and T.M. Kusky in this issue of the journal. In the first part of the discussion they emphasize correctly the 'path independence' of ellipse fabrics undergoing homogeneous strain, which is entirely in accord with the approach used by Wheeler. The subsequent discussion involves a misunderstanding of the physical meaning of the 'fabric ellipse/ellipsoid', which Wheeler discusses. 10 Refs.

**091428 ROCK STRESS MEASUREMENTS BY MEANS OF HYDRAULIC TESTS ON PRE-EXISTING FRACTURES AT GIDEA TEST SITE, SWEDEN.** This paper presents a summary of the theory, technique and the results from these measurements. Hydraulic tests on pre-existing fractures were conducted in a vertical borehole, in which hydraulic fracturing rock stress measurements had been conducted earlier, and the state of stress was determined at depths from 90 to 270 m. Two- and three-dimensional solutions of stress vs depth are presented, giving similar results, both in the magnitude and orientation of stresses. At depths between 100 and 150 m, the stress state is almost isotropic in a plane perpendicular to the borehole axis. A rotation of the maximum horizontal stress with depth was found. (Edited author abstract) 8 refs.

**091429 GRAVITY-INDUCED STRESSES IN STRATIFIED ROCK MASSES.** This paper presents closed-form solutions for the stress field induced by gravity in anisotropic and stratified rock masses. These rocks are assumed to be laterally restrained. The rock mass consists of finite mechanical units, each unit being modeled as a homogeneous, transversely isotropic or isotropic linearly elastic material. The following results are found. The nature of the gravity induced stress field in a stratified rock mass depends on the elastic properties of each rock unit and how these properties vary with depth. It is thermodynamically admissible for the induced horizontal stress component in a given stratified rock mass to exceed the vertical stress component in certain units and to be smaller in other units; this is not possible for the classical unstratified isotropic solution. Examples are presented to explore the nature of the gravity induced stress field in stratified rock masses. (Edited author abstract) 20 refs.

**091430 MICROSTRUCTURAL SHEAR CRITERIA ASSOCIATED WITH GRAIN-BOUNDARY SLIDING DURING DUCTILE DEFORMATION.** Experimental studies on rock analogies are described which establish that certain microstructures (diamond grain structures, tabular grain structures and asymmetric grain-boundary bulges) can be used to determine (i) if deformation was coaxial or non-coaxial and (ii) the sense of shear in zones of non-coaxial deformation. Mechanisms for the development of the structures are described which involve the linked operation of grain-boundary sliding and migration. (Author abstract) 29 refs.

**091431 INFLUENCE OF NEARBY FRACTURES ON STRESS MEASUREMENTS BY HYDRAULIC FRACTURING.** The interaction between a vertical borehole and a nearby vertical fracture is modeled by an infinite plane containing a circular hole and a crack. Analytical expressions for the stress field are obtained in terms of integral equations. Numerical results show how the stress distribution at the borehole is affected by fracture length (L), fracture-borehole separation (d), and the offset (l) of the crack centre from the minimum distance to the borehole. The crack offset can have a much stronger effect on the locations of the local minimum tangential stress at the hole boundary than the crack length and the fracture-borehole separation. The model is applied to stress measurements in a deep borehole in Northern Illinois granite. (Edited author abstract) 19 refs.

**091432 USE OF ASYMMETRIC PRESSURE SHADOWS IN MYLONITES TO DETERMINE THE SENSE OF SHEAR.** Asymmetric pressure shadows (APS) on both sides of a rigid porphyroclast are commonly observed in mylonites along the Median Tectonic Line (MTL) in Japan. Based on the shape analysis of APS in XZ section (parallel to the mylonitic lineation and normal to the mylonitic foliation), the following results were obtained: (1) the relative position of the APS with respect to a porphyroclast is not a reliable criterion for deducing the sense of shear; and (2) the drag angle ( $\beta$ ) of the shadow boundaries with respect to the mylonitic foliation in each quartered domain is diagnostic of the sense of shear; when the shearing is sinistral,  $\beta$  in upper right- and lower left-hand side of a porphyroclast is larger than  $\beta$  in upper left- and lower right-hand side, and vice versa for dextral shearing. These results demonstrate that the drag patterns of APS around porphyroclasts in mylonites are highly reliable indicators for the determination of the sense of shear. (Edited author abstract). 24

**091433 FRACTURE TOUGHNESS DETERMINATION OF LAYERED MATERIALS.** Layered materials, such as sedimentary rocks, are ubiquitous. A newly developed fracture toughness test specimen, which is semi-circular in shape and contains an edge-crack, is subjected to three-point-bend loading. The fracture load and the fracture energy of a layered rock are then measured with static tests, and the fracture toughness is determined using a stress intensity factor method, a compliance method and a J-integral based method. The results of all three methods agree satisfactorily showing that the fracture toughness determination using linear elastic fracture mechanics is valid for anisotropic rock materials. Specifically, the static fracture toughness of oil shale, which is a typical layered rock containing fossil fuel, was measured. (Edited author abstract) 39 refs.

**091434 BLIND ZONES IN THE ACQUISITION OF DISCONTINUITY ORIENTATION DATA.** In practice, discontinuity orientations are measured in rock core samples or they are mapped from rock exposures. The resulting data are biased because of the blind zones associated with each borehole or mapping surface. Although this concept of bias has been recognized in geologic mapping for a number of years, a procedure is still needed for calculating the size of a blind zone. This technical note shows how to quantitatively define the sizes of blind zones from the expected precision of orientation measurements so that their effects on site exploration data can be anticipated. 5 refs.

**091437 MONTE CARLO INVESTIGATION OF A PROPOSED SCREEN FOR NX-BOREHOLE JACK DATA.** F.E. Heuze has submitted a draft standard guide to the ASTM Subcommittee D18.12 on Rocks and Soils for using the NX-borehole ('Goodman') jack and calculating the in-situ deformation modulus of rock masses. One aspect of the proposed standard is a 'data screen' based on a full platen seating criterion. This article describes a computer simulation study that was performed to test the effect of the screen on the modulus estimate. The study demonstrates that the screen can actually degrade the quality of the estimate. It is concluded that the section of the proposed standard guide that deals with the screening of data should not be adopted. (Author abstract) 9 refs.

**Thermoanalysis** See RADIOACTIVE WASTES—Geological Repositories.

## Ultrasonic Effects

**091442 INVERSION OF ULTRASONIC WAVE VELOCITY MEASUREMENTS TO OBTAIN THE MICROCRACK ORIENTATION DISTRIBUTION FUNCTION IN ROCKS.** Ultrasonic wave velocities in rock are reduced significantly by the presence of microcracks. In general, these microcracks are not randomly orientated and the rock displays an elastic anisotropy determined by the shape and content of the cracks and by the crack orientation distribution function. This function gives the probability of a crack having a given orientation with respect to a set of axes fixed in the rock, and is used to calculate the variation of elastic wave velocity with propagation direction. The coefficients,  $W_{lmn}$ , of a series expansion of the crack orientation distribution function in generalized spherical harmonics can be obtained in order  $l=4$  from the angular variation of the ultrasonic wave velocity. This allows construction of microfracture pole figures which may be compared with those obtained by petrofabric examination. The theory is applied to the measurements of Thill, Willard and Bur on Salsbury granite. (Edited author abstract) 20 refs.

## Vibrations

**091443 FINITE ELEMENT ANALYSIS OF VIBRATIONS INDUCED BY PROPAGATING WAVES GENERATED BY TUNNEL BLASTING.** An example of a new tunnel excavated below an existing tunnel has been studied. Even though this problem is three dimensional in nature, due to the large computational efforts involved in three dimensional dynamic analysis, a two dimensional finite element analysis has been adopted. A pseudo-plane strain concept has been used since it has been found that the results obtained using such an approach are more realistic than the conventional plane strain analysis. It is concluded that results from such a numerical analysis could complement the field investigations to produce guidelines for safe and controlled blasting. (Edited author abstract) 29 refs.

## Wear

**091445 ABRASION TESTING AND ARMOUR-STONE DEGRADATION.** A cylindrical tumbling mill apparatus is used to provide weight loss and shape change data on rock fragment abrasion from four experiments. Weight loss data for the four limestone samples confirm the reproducibility of the test conditions and of the abrasion resistance index value which had been reported previously for this rock type. Progressive shape changes of subsamples are analyzed using recently developed automated image analysis techniques and computer methods based on Fourier and Fractal shape descriptors. A theoretical relationship between weight loss, revolutions in the mill and surface roughness is developed. Weight loss-time, and asperity roughness-time relationships are determined and their application to armourstone rounding is discussed. Examples from a hard and a soft limestone are given to illustrate the use of the tumbling mill aggregate abrasion test in the prediction of wear or armourstone after a certain number of years in service. **091448 WATER-JET-ASSISTED DRAG BIT CUTTING IN MEDIUM-STRENGTH ROCK.** This Bureau of Mines report reviews hypotheses for the mechanism by which water jets reduce the specific energy of cutting for drag bits. Several of these hypotheses are shown to be inconsistent with published evidence and new observations. The notion of a limiting cutting speed, above which

water jets would be incapable of rendering assistance, is shown to be improbable. The hypothesis that seems most plausible is that specific energy reductions are mainly due to the erosion of crushed materials from in front of the bit. This hypothesis leads to a prediction that, for a given rock type and jet-bit configuration at a constant depth of cut, the reduction in bit forces should be a function of  $dW/dx$ , the jet energy spent per unit length of cut. This dependence upon  $dW/dx$  is shown to be consistent with other workers' results. (Author abstract) 18 refs.

Geier, J.E. (Univ of California, Berkeley, CA, USA); Hood, M.; Thimons, E.D. *Inf Circ US Bur Mines* 9164 1987 14p.

**091449 ELECTROCHEMICAL EFFECTS ON ROCK DRILLING.** Drilling tests were conducted on Sioux quartzite with  $AlCl_3$ ,  $ZrCl_4$ ,  $CaCl_2$ , and  $NaCl$  solution concentrations and on Westerly granite with  $AlCl_3$  solution concentrations below, at, and above their respective ZPC concentrations using a 16-mm diamond impregnated coring bit. Results show that surface tension reducers are efficient in chemical crack propagation. However, when drilling is regarded as activated cracking that involves the catastrophic growth of microcracks into more destructive ones, it is then possible that the interfacial tension, or surface energy, must first go up to a critical tension before a rock fragment separates with a lowering of interfacial tension. This distinction between the kinetic process of drilling and the thermodynamic state of crack formation can explain why an increase in interfacial tension can facilitate drilling rate by lowering the energy barrier for rock fragmentation. 2 refs.

Engelmann, W.H. (US Dep of Interior, Minneapolis, MN, USA); Watson, P.J.; Tuzinski, P.A.; Pahlman, J.E.; Khalafalla, S.E. *J Electrochem Soc* v 135 n 4 Apr 1988 p 1043-1044.

**091450 OBSERVATION OF CRACKS AT THE BOTTOM OF PERCUSSION AND DIAMOND DRILL HOLES.** The study described in this paper demonstrates that indentation fracture development beneath a commonly used percussive chisel bit is more complex than has been previously described. Observed crack systems resemble those due to a combination of Hertzian (spherical indenter) and sharp indenter stress fields. Work described in this paper shows that diamond core drilling does not produce an extensive fractured zone around the active cutting elements. The zone of fracture is very localized and can only be observed with the aid of a microscope. These results are in agreement with the findings of Graham. 19 refs.

**091451 ZETA POTENTIAL CONTROL FOR SIMULTANEOUS ENHANCEMENT OF PENETRATION RATES AND BIT LIFE IN ROCK DRILLING.** In pursuit of innovative methods to improve mining productivity, the Bureau of Mines is investigating the use of inorganic salts as drilling fluid additives for penetration enhancement. Laboratory diamond drilling tests were performed on Westerly Granite with aluminum chloride solutions and on Sioux Quartzite with aluminum nitrate and aluminum, calcium, sodium, and zirconium chloride solutions as drilling fluid additives. These drilling results were compared with the average drilling performance using distilled, deionized water on Sioux Quartzite (12 replicate tests) and Westerly Granite (3 replicate tests). Maximum increases in penetration per given time and bit life were obtained when drilling with zero point of charge (ZPC) concentration solutions of each additive. For Sioux Quartzite, maximum increases in penetration and bit life ranged from 96 to 115 pct and 64 to 99 pct, respectively. For Westerly Granite, maximum increases in penetration of 155 and 165 pct and bit life of 109 and 136 pct were obtained at or near ZPC aluminum chloride concentra-

tions of quartz ( $7.3 \times 10^{-7}$  mol/L  $AlCl_3$ ) and alkali feldspars ( $1.1$  to  $1.5 \times 10^{-6}$  mol/L  $AlCl_3$ ), respectively. This simultaneous increase in penetration per time together with extended bit life should result in increased productivity and reduced bit costs. (Author abstract) 17 refs.

## Efficiency

**091453 DRILLING FOR HOT DRY ROCK RESERVOIRS.** A drilling group evaluated techniques suitable for drilling inclined boreholes, of controlled geometry, to reach temperature of 200 to 250 degrees C in crystalline rock. They concluded that there is no fundamental reason why holes for Hot Dry Rock (HDR) projects cannot be drilled and completed successfully using techniques already available, and that further development work should aim at risk and cost reduction rather than new techniques. They stressed the need for meticulous planning and careful engineering in any HDR drilling operation. (Edited author abstract) 7 refs.

## Measurements

**091454 BOREHOLE MEASUREMENTS IN THE FIELD OF HOT DRY ROCK EXPERIMENTS.** The authors examined the value of different types of borehole logging in the context of Hot Dry Rock developments and considered the limitations of current techniques and the scope for further development. They recommended that the main development effort should concentrate on methods of fracture detection, both at the borehole wall and in the far field. They further recommended that such work would best be done as part of a collaborative international effort. (Edited author abstract) 8 refs.

## Remote Sensing

**091455 ELECTROMAGNETIC LOCATING TECHNOLOGY ENHANCES NO-DIG OPERATIONS.** Trenchless or no-dig operations are often conducted 'in the dark', where knowledge of progress or problems is only available by measurement or by feel. Some light has, however, been brought to bear on the subject by the development of sonde technology. Signal emitting sondes can transmit signals through rock or soil from depths down to 20m, which are then detected by a receiver. Because of the compact size of sondes, as small as  $13 \times 64$ mm, users of horizontal boring tools have found they can fit them directly to or just behind their equipment.

Consequently, in the event of failure underground, the position of the tool can be fixed exactly and arrangements made to retrieve it.

Garnet, Andy (Radiodetection Ltd). *Civ Eng (London)* Oct 1987 p 53.

## Stresses

**091456 ROTARY PERCUSSION FORCES AFFECTING A DRILLING RATE OF BIT FOR ROCK MASS.** The drilling rate of a rotary percussion drill bit depends on the revolving energy and the impact energy of the drifter, as well as the characteristics of rock mass. The rotary percussion drill tests were executed in-situ for 13 kinds of rock mass using 12 actual drill machines to clarify the interrelations between them. The drilling rate has been expressed as a function of the revolving energy, the impact energy, the bit diameter, the coefficient of crack of rock mass and the shore hardness or the amount of Los Angeles abrasion or the radial compressive strength of rock specimen. On the other hand, the rock mass properties could be determined by measuring the drilling rate of a standard rotary percussion drill machine. (Author abstract) 8 refs.

**091457 INVESTIGATION OF THE STRESS-STRAINED STATE AND STRENGTH OF ROCK CUTTING TOOLS.** The stress-strained state and strength of hard alloy inserts are calculated by the method of finite elements depending on their orientation during cutting. Calculated fields of displacements, deformations and stresses in the inserts from the action of the concentrated load applied to the angle vertex of cutting edges are obtained for different angles of orientation. Zones of dangerous tensile stresses are determined in this case. Calculations for hard alloy inserts are analyzed. Structural and technological parameters of inserts are evaluated for their effect of the stress-strained state and strength. Recommendations are made to improve the structure of inserts and selection of the angle of their fixation in the holder. Basic requirements regarding the optimal insert are formulated. **091458 WAYS TO IMPROVE THE DRILLING EFFECTIVENESS OF ROCK BITS BY A TRIBOLOGICAL METHOD.** Wear tests on the main bearings of 8.5 inch XHP 3 rock bits were performed, from which it is concluded that the way to improve the drilling effectiveness for the rock bits is to set drilling pressure and rotary speed properly, and to develop a new type of grease for rock bits which can bear a higher temperature than conventional grease. In addition, it is also shown that an inexpensive copper alloy can take the place of expensive Ag85Mn15 as an anti-wear material in the bearing, so that the production cost for the rock bits can be reduced. ## Computer Applications

**091461 COMPUTERIZED DRILLING IN DEEP MINING.** One should remember that even though computerized drill rigs may work quite independently after the button is pushed, someone is still required to push the button. In this respect, aspects such as work motivation and remuneration have to be given new and close consideration. A DATA-driller should be aware of why the various work phases are carried out, what is required to ensure the excavation quality we referred to earlier, and what the following phase in the work cycle is.

## Design

**091462 STUDIES ON THE DESIGN OF OIL HYDRAULIC ROCK DRILL (2ND REPORT).** Oil hydraulic rock drills have been used in the field of mining and public works. This paper treats the percussion type rock drill which is driven by the interaction of a piston and valve. Sensitivity analysis is applied to an investigation of the influence of design parameters on the performance of the drill. It is demonstrated that the effect of leakage from the rear chamber of the piston is more sensitive to the performance. For the purpose of optimum design the influence of the construction of the drill is also indicated using dimensions of the piston as a variable. (Edited author abstract) In Japanese. 1 ref.

**091468 VARIATION OF PORE WATER WITH DEFORMATION BEHAVIOUR OF ROCKS UNDER VARIOUS EFFECTIVE CONFINING PRESSURES.** The triaxial compression test for some kinds of rocks was carried out, monitoring variation of pore water with deformation behaviour by use of a hydraulic testing machine equipped with a servo-control system for triaxial loading. Differential stress and variation of pore water-strain curves for rock samples were determined at the range within 10% of a value of sample deformation under the condition of confining pressure and pore pressure

extending up to 80MPa. The experiment showed that it was possible to monitor variation of pore water following the deformation behaviour of samples, and these phenomena were divided into two types depending on the deformation behaviour. One type obtained primarily under the brittle deformation behaviour, possessed a turning point between outflow and inflow of pore water which existed before a point of maximum differential stress on stress-strain curves. This turning point approximately agreed with the position occurring dilatancy of volumetric strain. In regard to the other type obtained under the ductile deformation behaviour, there was no the turning point in the majority of cases, although dilatancy occurred on volumetric strain. It is presumed that this discrepancy is largely concerned with fracture mode in a rock specimen. (Author abstract) 7 refs. In Japanese.

**091470 BEHAVIOUR SIMILARITY OF MOHR'S ROCK STRENGTH DIAGRAMS.** On the basis of comprehensive analysis of a number of triaxial test data, we find: 1) There exists a remarkable similarity among strength curves obtained from tests when rock samples with different origins and structures are tested under different loading conditions and loading modes; 2) there exists a high correlation between the shear strength coefficient (A) and the normal compressive strength coefficient (B), and between the internal friction coefficient (f) and the cohesion coefficient (K), on the failure surfaces of rocks; and 3) in logarithmic coordinates the rock strength diagrams are represented by parallel straight lines. Empirical formulae have been obtained by exponential regression. If the uniaxial compressive strength,  $R_c$ , is measured, the values of shear strength at any given normal compressive strength can be obtained, and the rock strength diagrams can be easily determined. Test work for determining rock strength diagrams is greatly simplified, and the amount of calculation has been reduced for determining cohesive force (C), and the angle of internal friction ( $\phi$ ). **091471 NEW METHOD FOR MEASURING TWO-DIMENSIONAL CHANGE OF IN-SITU STRESSES DURING EXCAVATIONS: A STUDY ON THE METHOD FOR MEASURING IN-SITU STRESS CHANGES WITH PRESSURE CELL (1ST REPORT).** The method uses a cylindrical pressure cell with eight strain gages glued to the inner wall of the cell which is inserted in a borehole with non-contraction type grouting material. A special merit of this method lies in the internal pressure test which is carried out, using the measuring instrument itself in order to know the mechanical interaction between the measuring system and the rock mass. Utilizing the information on the deformation modulus of the rock mass obtained in the internal pressure test, two-dimensional changes of in-situ stresses are measured with the least squares method on the circumfer-

ential strain distribution around the inner wall of the pressure cell. Results of laboratory tests in uniaxial and biaxial compression are summarized. (Edited author abstract) In Japanese. 4 refs.

**091472 STUDY OF ACOUSTIC EMISSION DURING DEFORMATION OF ROCKS UNDER CONDITIONS OF A COMPLEX AXISYMMETRIC STRESSED STATE.** The authors carried out studies of rock specimens during their deformation under complex stressed conditions with simultaneous recording of mechanical properties, and ultrasonic and AE signal propagation rates. This will make it possible to reveal the laws governing microcrack formation in the high strain region. A study of the laws for acoustic emission (AE) behavior with a complex stressed state has shown that the nature of the dependence for the number of AE signals depends markedly on the ratio of stressed state components for the specimen. The existence of a range for the maximum AE intensity is due to formation of cracks of tensile origin. The range of minimum AE intensity corresponds to the shear mechanism of deformation with a growing residual increase in material volume (quasiplastic deformation). 7 refs.

**091477 PLASMA METHOD OF REINFORCEMENT OF SOFT ROCKS AND CALCULATIONS FOR THE RESULTING STRUCTURES.** Thermal reinforcement of soft rocks is employed for strengthening embankments, support walls, foundations, and other supporting and containment systems in underground construction. Rocks around boreholes are heated by supplying a heat carrier through the hole. A wider application of thermal reinforcement of rocks has been limited by the long time (several days) of the baking process, as well as the insufficient strength of the resulting structural components. The main cause of this is the practically low (not more than 1000°C) temperatures of the heat carrier. With the plasma method of thermal reinforcement, this shortcoming can be overcome because the mean mass temperature of the heat carrier can be raised to 10,000° C. 4 refs.

Zadvornev, G.A. (Military Engineering Acad, Togliatti, USSR); Novikov, V.F. *Sov Min Sci* v 22 n 6 Nov-Dec 1986 p 434-440.

**091478 DISTINCT ELEMENT METHOD - APPLICATION TO ANALYSE SLIDING AND TOPPLING FAILURES.** The distinct element method proposed by Cundall in 1971 has been applied to simulate the process of sliding and toppling failures. To check the accuracy of the computer simulation, a series of physical experiments as well as analytical calculations have also been carried out. Two problems are treated in this paper: one is the sliding and/or toppling behaviors of jointed pillars; the other is the behavior of plane sliding of a quadrangle block in relation to the force required to arrest its movement. Excellent agreements between the simulated results and the physical test results indicate that the distinct element method is effective to solve the problems concerning discontinuous rock mass. (Edited author abstract) 8 refs.

**091480 INFLUENCE OF OUT-OF-PLANE STRESS ON A PLANE STRAIN PROBLEM IN ROCK MECHANICS.** This paper considers the excavation of a cylindrical cavity in a uniformly prestressed mass of brittle Mohr-Coulomb rock. Previous plane strain displacement solutions have assumed that the out-of-plane stress remains the intermediate principal stress at all points. It is here shown that when this assumption breaks down, an inner plastic zone is created in which  $\sigma_r < \sigma_z = \sigma_\theta$ . A displacement solution is given for this case, using a variable-dilation plastic flow rule, and results are compared with the previous solution for specific problems. A

significant difference is observed only for problems involving a large drop in strength upon yield. (Author abstract) 7 refs.

**091481 CHARACTERIZING ROCK JOINT GEOMETRY WITH JOINT SYSTEM MODELS.** Two major approaches have emerged to describe the assemblage of geometric joint characteristics in a rock mass: the traditional disaggregate characterization and the more recent aggregate characterization. In the former, each joint characteristic is described separately. In the latter the independence of joint characteristics is captured through the formulation joint system models. A particular joint system model represents a typical geometry. The individual characteristics are still stochastically described but their interdependence is specified. The joint system models which represent the newest developments and to which the authors and their co-workers at MIT have made significant contributions will be presented in greater detail. 70 refs.

**091482 CASAGRANDE RESISTANCE ENVELOPES FOR ROCK AND ROCKFILL SLOPES HAVING CIRCULAR SLIP SURFACES.** A series of Casagrande resistance envelopes are presented for use in the preliminary design and evaluation of uniform rock and rockfill slopes. The influence of tension cracks on the safety factors for such slopes is examined. A comparison is also made between the safety factors obtained using the resistance envelope method and those obtained using published stability charts for rockfill slopes having nonlinear shear strength envelopes. (Author abstract) 11 refs.

Baikie, L.D. (Technical Univ of Nova Scotia, Halifax, NS, Can). *Can Geotech J* v 25 n 1 Feb 1988 p 42-49.

**091483 INFLUENCE OF THIN LOW-VELOCITY LAYER ON ELASTIC WAVES.** It is important for in-site rock mass estimation and fractured zone exploration with seismic method to clarify the elastic wave propagation in rock mass including thin low-velocity layer such as water-saturated cracks and thin fractured zone. In-site P wave velocity is commonly used for estimation of rock mass including cracks, because P wave velocity decreases as the thickness of cracks and the number of them increase. But the time average formula is not applicable to in-site rock mass including cracks. The reason is as follows. The wave length of P wave used for rock mass estimation is much longer than the thickness of the cracks. Therefore, transmitted wave is formed by the superposition of many waves. The one is the wave which transmits without any reflection at the contact plane between rock and the material in the cracks, and the others are the waves which have multiple reflections within the cracks in their wave paths. (Edited author abstract) In Japanese. 1 ref.

**091485 SEISMIC-ACOUSTIC STUDIES OF DYNAMIC PHENOMENA IN THE PRODUCTION UNIT 'MECHEKUGOL'.** Seismic-acoustic studies for predicting failure of rocks at the Production Unit 'Mechekugol' in the mine make it possible to obtain information about the condition of the intact rock mass using active methods, i.e., the excitation and recording of elastic waves from an 'artificial source' and passive methods, i.e., observation of seismic-acoustic emissions occurring spontaneously during failure of rocks. Artificially excited and spontaneously occurring elastic waves carry all the information about material properties and about the failure process itself. Recording of acoustic signal parameters and their range is possible depending upon which instruments are used. In studying dynamic phenomena and sudden outbursts in the research center of the 'Mechekugol' enterprise use is made of the Danish seismic-acoustic instrument system of the firm Bruel and Kjaer, which makes it possible to carry out various studies. 4 refs.

Szucz, I. *Sov Min Sci* v 23 n 2 Mar-Apr 1987 p 120-125.

**091486 BREAKING EFFECT OF AN EXPLOSION DURING PREPARATION OF FACING STONE BLOCKS.** Use of explosive energy of a detonating fuse (DF) during preparation of facing stone blocks under certain conditions leads to formation in the rock mass of different types of irreversible strains. They are basically cracks normal to breaking, occurring in the vicinity of the blast-hole during propagation of rarefaction waves in the rock mass, and fatigue cracks connected with development of micro- and macrostructural defects with each cycle of explosive loading. This article considers the effect of an intense load on the radius of the zone of disturbed continuity for the space around the blast-hole (R) in different rocks with explosion of single ( $n=1$ ) and double ( $n=2$ ) lengths of DF in blast-holes 25, 32m and 44 mm in diameter. 4 refs.

**091487 GENERAL SLIP MODEL FOR ROCK MECHANICS.** In situ testing of rock to obtain its deformation modulus is a recognized procedure in the geomechanical investigation of dam sites and of the bedrock formation for other large structures. In such tests the deformation response to loading is found to be reasonably linear, but during unloading the response is often strongly curved. On reloading, the load-deformation curve may rejoin the original loading line, but it may also join at the point where unloading was started. The strong hysteresis effect shows that a considerable amount of energy is dissipated and it is generally agreed that this is due to the presence of joints or cracks. In the present study, the rock is modelled using springs and slip models both in parallel and in series. In the first part a slip model is described which is similar to but more general than a model described by B.H.G. Brady et al. In the second part, models are combined to produce a more realistic picture of practical behaviour of a rock mass. 2 refs.

**091489 ANALYSIS OF ROCK REINFORCEMENT USING FINITE DIFFERENCE METHODS.** Large-scale rock reinforcement offers the prospect of flexible and effective control of rock displacement around large open mine excavations. Although the technology of rock reinforcement is well developed, reinforcement analysis and design methods are not. Analysis is presented here for the mechanics of two models of rock reinforcement, one based on local action of a reinforcing element at a slipping joint, the other on spatially-extensive action in rock subject to diffuse deformation. The principles of some finite difference methods of analysis of stress and displacement are outlined. The performance of a code modeling spatially-extensive reinforcement is examined in a parameter study of slope hangingwall reinforcement using long grouted cables. (Author abstract) 18 refs.

**091490 PALEOSTRESS DETERMINATION IN A ROCK BY A FRACTOGRAPHIC METHOD.** A fractographic technique hitherto used in ceramics for the evaluation of fracture stress is adapted to calculate fracture paleostresses in rocks. An example from a granite in East Sinai is analyzed. The results obtained for the ranges of local paleofracture stress, severest flaw size and initial stress intensity factor agree reasonably well with previous evaluations of fracture stresses in granite and with direct observations of the rock's grain size. (Author abstract) 33 refs.

**091491 FULLY DEFORMABLE DISCRETE ELEMENT ANALYSIS USING A FINITE ELEMENT APPROACH.** A method of analysis is presented for problems in which the deformation of the individual blocks play a significant role. The blocks are modeled as single quadrilateral elements and a constitutive model has been presented for computing the contact forces. In order to illustrate the influence of the deformation of the individual blocks two examples have been presented. The results of the analysis with deformable blocks and with rigid blocks are compared. These examples clearly demonstrate the importance of the deformation of blocks in the class of problems represented by these two examples. (Author abstract). 13 Refs.

**091493 COMPUTERIZED POLE CONCENTRATION GRAPHS USING THE WULF STEREOGRAPHIC PROJECTION.** With the development of computer techniques, it is possible to draw contours of pole concentration with computers. However, those programs are coded by using the principle of traditional hemisphere projection with manual drawing methods. When a counting circle is across the boundary, compensation counting is necessary from its corresponding circle, which provides complication both in counting and calculation. If an approximate calculation is used, certain errors may occur. By full utilization of the property of the Wulff projection, a large hemisphere is adopted to eliminate the counting of the corresponding circle and to provide a clear in concept, simple in formula, accurate in counting and fast in calculating method. 2 refs.

**Computer Applications**

**091494 ROCK ENGINEERING SOFTWARE.** The Commission on Computer Programs of the International Society for Rock Mechanics has attempted to produce a list of programs by sending questionnaires worldwide, and asking for short descriptions of the programs in question. The response has been very warm, and a large number of program descriptions have been received. The list should give an overview of the current state of development and application of computer programs in universities, research institutions and companies. Furthermore, the list should help towards information exchange between the various institutions, and encourage the further use of numerical methods. Commercial aspects have not been taken into account in producing the list. Program descriptions are given, and program abstracts in each section are ordered alphabetically according to country of origin. Programs for a given country are ordered by their code names.

**Elasticity**

**091495 TWO-DIMENSIONAL DIRECT BOUNDARY INTEGRAL METHOD FOR ELASTODYNAMICS.** This paper presents the mathematical and numerical development of a two-dimensional boundary element model for elastodynamics problems in rock mechanics. The model is based on a time-domain formulation of the direct boundary integral method, and is capable of computing the transient response of an underground excavation to dynamic loading conditions. All boundary contours are approximated by straight line segments, joined end to end, and the displacements and tractions within a time step are assumed to vary quadratically over each segment. Two example problems for a suddenly pressurized circular hole in an infinite plate are used to illustrate the numerical procedures described in the paper. (Edited author abstract). 19 Refs.

**091496 IN-SITU TESTS USING CRACK-DETECTOR WITH ROTATING PROBES FOR MEASURING SONIC VELOCITY (2ND REPORT) - STUDIES ON CRACK DISTRIBUTION AND SONIC VELOC-**

**ITY CHANGE IN ROCKS (3RD REPORT).** A crack detector has been developed for measuring the distribution of open cracks and the change in sonic velocity in rock masses. In-site measurements have been performed in a tunnel and a quarry. In order to confirm what part of a retaining wall was damaged by an earthquake, the distribution of open cracks and the change in sonic velocity were measured in a borehole drilled in the retaining wall. From the results of measurement, it was clear that the crack zone in the retaining wall lies on the extension of the boundary between the natural ground and the bank. These findings show that use of the crack detector is practical when the distribution of open cracks corresponds to the undetectable area of measurements for the design of rock and concrete structures. **091497 IMPULSIVE PROPERTIES OF FALLING ROCKS ON SAND-LAYERS BY MEANS OF CUNDALL'S DISCRETE BLOCK METHOD.** In this study, the transmission mechanism of impulsive force of a falling rock on a sand layer was investigated by means of Cundall's discrete block method. At first, a falling rock and a sand layer were modelled by elements assembled of rigid cylinders, springs and dashpots, then effects of basic parameters such as spring and damping constants on the impulsive force were discussed under the numerical analysis as a two dimensional problem. Secondly, to explain the real behavior better, the discrete block model was extended to a three dimensional problem using the character of the sand based on experimental results. Finally, it was shown that the transmission mechanism of impulsive force by a falling rock in this method agrees with that in experimental results on various conditions. **091498 TOWARDS A METHODOLOGY FOR ROCK MECHANICS MODELLING.** Rock mechanics models fall into the class of "data-limited problems"; one seldom knows enough about a rock mass to model it unambiguously. Modellers are beginning to realize that data-limited problems require a very different modelling approach from that developed in, for example, electrical or aerospace engineering. It follows that one cannot use models in rock mechanics in a conventional way, and that there is a need to adopt a distinctive and appropriate methodology for rock mechanics modelling. Some guidelines and heuristics, which may be considered as the first steps towards developing such a methodology, are presented. Three case studies are then used to illustrate the application, in practice, of these ideas. (Author abstract). 8 Refs.

**091499 FORMULATION OF A THREE-DIMENSIONAL DISTINCT ELEMENT MODEL - PART I. A SCHEME TO DETECT AND REPRESENT CONTACTS IN A SYSTEM COMPOSED OF MANY POLYHEDRAL BLOCKS.** The distinct element method has advanced to a stage where the complex mechanical interactions of a discontinuous system can be modelled in three dimensions. An important component is the formulation of a robust and rapid technique to detect and categorize contacts between three-dimensional particles. The technique, described in Part I of this paper, can detect the contact between blocks of any arbitrary shape (convex or concave) and represent the geometrical and physical characteristics prescribed for the contact (e.g. three-dimensional rock joint behaviour). The method utilizes an

efficient data structure which permits the rapid calculation on a personal computer of systems involving several hundred particles. (Author abstract). 4 Refs.

**091500 FORMULATION OF A THREE-DIMENSIONAL DISTINCT ELEMENT MODEL-PART II. MECHANICAL CALCULATIONS FOR MOTION AND INTERACTION OF A SYSTEM COMPOSED OF MANY POLYHEDRAL BLOCKS.** A three-dimensional formulation of the distinct element method is embodied in computer program 3DEC, which has been adopted to run on a personal computer. This formulation is based on a dynamic (time domain) solution algorithm which solves the equations of motion of a three-dimensional block system by an explicit finite-difference scheme. The scheme is well suited in rock mechanics studies to determine if a discontinuous rock mass will fail under a given set of applied loads. Part II of this paper describes the mechanical calculations of rigid body motion and block interaction. Part II also presents the technique used in 3DEC to generate a three-dimensional model for rock mechanics analysis. Several examples are provided which demonstrate the capabilities of 3DEC and the size of problem that can be analyzed on a personal computer. The examples emphasize the use of microcomputer graphics to assess model results. (Author abstract). 13 Refs.

Hart, R. (Itasca Consulting Group Inc, Minneapolis, MN, USA); Cundall, P.A.; Lemos, J. *Int J Rock Mech Min Sci Geomech Abstr* v 25 n 3 Jun 1988 p 117-125.

**091501 GENERATING A BLOCKY ROCK MASS.** A block generator has been developed to reconstruct the three-dimensional block structure around excavations in rock. The blocky rock mass defined by the generator is an essential input to study of the stability of the jointed rock masses in the vicinity of excavations, using either single block stability analysis techniques, or block model codes. The generation method enables us to include knowledge of the tectonic history of the rock mass in order to make maximum use of the usually limited data on the fracture sets. A computer language BGL (Block Generation Language) has been developed to facilitate application of the method. The main features of BGL are outlined and a tutorial example is presented. Finally, the problem of graphically displaying the joint systems of three-dimensional blocky rock masses is discussed, and a novel graphical display method is presented. (Edited author abstract). 37 Refs.

#### Permafrost

**091502 DYNAMICS OF THAWING PERMAFROST ROCKS FOR MINING EXCAVATIONS.** Effective operation and evaluation of support systems of mine workings in permafrost require predictions of the dynamics of wall thawing by warm air. Several investigations have been done in this area, but all have the same shortcoming: The studies were done for a constant positive temperature of air in the mine. In practice, however, variable temperatures should be considered, since the workings of all underground mines in the northeastern USSR operate all year round in sign-variable temperature conditions. The present study addresses the problem by algorithmic computer simulation. 8 refs.

#### Plasticity

**091503 FINITE STRAIN ROCK PLASTICITY: STRESS TRIAXIALITY, PRESSURE, AND TEMPERATURE EFFECTS.** An elasto-plasticity theory is used to model the deformation of geological materials

under various confining pressures and moderate temperatures. Based on this theory, dilatancy (i.e., inelastic volumetric expansion) of an intact granite is studied under conventional triaxial stress states. The effect of pressure and temperature on the magnitude of dilation and on the stress (measured relative to the peak stress) at the onset of dilatancy is investigated. It is found that, consistent with experimental data, the theory predicts this stress to be about 50% of the peak stress, but its specific value depends on pressure and temperature. As an illustration, stress-strain curves for intact granite at relatively shallow crustal depths are predicted for application to the study of crustal deformation and the prediction of fault behavior. (Edited author abstract) 61 refs.

#### Pore Pressure

**091504 MESURE DE L'INFLUENCE DE LA PRESSION SUR LA PROPAGATION DE FISSURE DANS LES ROCHES.** [Measuring the Influence of Pressure on Crack Propagation in Rocks]. The influence of pressure on fissure propagation by opening (mode I) in a compact fine-grained rock (Comblanchian limestone) and by plane shearing (mode II) in a stratified rock (slaty shale) has been revealed and measured. In both cases, a linear relation was found between the critical-stress intensity factor and pressure. This relation is illustrated for mode II by applying solid friction effects. (Author abstract) In French. 34 refs.

Biret, F. (CNRS, Talence, Fr); Valentin, G. *Rev Inst Fr Pet* v 42 n 6 Nov-Dec 1987 p 807-825.

#### Porosity

**091505 COMPLIANCE EFFECTS ON PORE PRESSURE DISTRIBUTION.** Initially the rock mass considered has directional attributes caused by joint sets. This means that the discontinuous material is anisotropic to deformation response. If the joints are aligned either parallel or perpendicular to the applied loads, the modes of stress distribution are different and the compliances are lower or upper bound values respectively. For a specific model representing either parallel or perpendicular pore alignment, the relation between applied load and induced pore pressure for each model is different. Terzaghi's effective stress law is a compatibility model, while Bishop and Skempton's induced pore pressure relations are equilibrium models. The difference between stress transfer and stress redistribution is examined. The structural compliance of the soil or rock mass frame is more important than that of the intact material when the porosity is greater than 10%. When porosity is less than 5%, the intact rock material compliance relative to fluid compliance controls the stress distribution between the fluid and intact rock material. (Author abstract) 9 refs.

**091506 GENERAL TENDENCY OF INITIAL STRESS STATE IN JAPAN WITH THE DATA OF IN-SITU MEASUREMENTS.** An initial stress state considerably affects the stability of an underground opening. In this paper, the authors collect and arrange the data measured at 41 points in Japan by stress relief methods, and discuss the general tendency of initial stress state in Japan. The results exhibit that the magnitude of the vertical stress is close to the overlying rock weight in the most cases, however, the horizontal stress varies with directions and the magnitude of minimum horizontal stress often exceeds that of the vertical stress. The directions of minimum horizontal stresses seem to be consistent with those implied by the geodetic strains. Therefore, the large horizontal compressive stresses in Japan can be affected greatly by crustal movements. (Author abstract). 26 Refs. In Japanese.

**091507 ELASTOPLASTIC MODEL WITH DAMAGE FOR STRAIN SOFTENING GEOMATERIALS.** The paper examines certain important aspects of a rate independent model that accounts for distributed damage due to microcrack growth. Material behavior is considered as a mixture of two elastic-plastic interacting components, one termed topical, and the other termed damaged. The mechanisms of failure are considered and discussed with respect to multiaxial stress paths. An explanation of failure, at the microlevel, is given. A series of laboratory tests on a concrete are used to illustrate the development of failure. (Edited author abstract) 46 refs.

**Stability**

**091508 STATIC ANALYSIS OF THE STABILITY OF THREE-DIMENSIONAL BLOCKY SYSTEMS AROUND EXCAVATIONS IN ROCK.** This paper describes the development of a procedure for three-dimensional analysis of the static stability of an assembly of polyhedral rock blocks around an underground excavation. The method is based on graph theory, and involves systematic analysis of the spatial arrangement of the blocks. The relationship between a structured graph and block system topology is investigated in order to identify removable blocks, i.e. blocks that are geometrically and kinematically free to become detached from the remaining system of blocks. Algorithms to construct paths of removable blocks from a given block system are described, together with post-processing procedures for creating graphic computer displays of the blocky system, and of the stable and unstable blocks. **091509 COMPLETE ELASTIC MODEL FOR FLUID-INDUCED AND IN-SITU GENERATED STRESSES WITH THE PRESENCE OF A BOREHOLE.** This paper develops a complete linear elastic model of a square plate with a circular hole in the middle. The model takes into account two horizontal in-situ stresses, the axial stress and stresses due to fluid flow in the borehole and inside the porous plate. The model contains solutions for both plane strain and plane stress conditions. The model has many applications in applied mechanics. In rock mechanics, it gives the total stress field, including the effects to the fluid pressure inside the rock. It may also be used to model the mechanical response of chemical absorption processes like clay swelling or thermal effects. One particular application of the model is in wellbore stability problems as applied to the petroleum and mining industry. Here, the knowledge of the stress fields is of utmost importance for a safe and economical operation. (Edited author abstract) 11 refs.

**091511 THREE-DIMENSIONAL STRESS ANALYSIS: A FORMULATION FOR MINING PROBLEMS.** Mathematical and computational aspects of a three-dimensional boundary element formulation designed specifically for application to mining rock mechanics problems are described. Stress analysis of mining geometries differs in many respects from equivalent analyses of civil or mechanical engineering. These differences are highlighted and the manner in which these differences are accommodated by the formulation is described. The formulation has been implemented into a program BEAP (Boundary Element Analysis Package). A test problem is presented and compared with other formulations. Design goals for the program are discussed. A practical mining example is presented. (Edited author abstract) 18 refs.

**Structural Analysis** See GEOPHYSICS—Rock Properties.

**Viscoplasticity**

**091512 VISCOPLASTIC MODEL FOR SOFT ROCK.** The aim of the model is to represent the main features of soft or brittle rock strata, using a small number of physically-meaningful material parameters. The yield surface is based on either the Mohr-Coulomb or Hoek-Brown criterion, and a simple small-dilation flow rule allows the implicit algorithm of elasto-viscoplasticity to be used. Elastic-brittle plastic behaviour is modelled, resulting in stress discontinuities across the interface between intact and failed rock. The effects of lamination and jointing are taken into account. Results are presented for a tunnelling problem with axial symmetry. (Author abstract) 13 refs.

**091513 MECHANICAL DESIGN OF A MEDIUM DUTY STONE SLICING MACHINE.** The article presented here deals with the design of a medium duty stone slicing machine. It is claimed to be an original work in the field of stone slicing. The machine is essentially a compound slider crank mechanism with two degrees of freedom. It incorporates an ingenious blade tensioning and holding device. Power required for machine is 40 HP, with the production capacity being a maximum of 16 slices of 40×40×2 cm per two hours. The design is optimized for processing granite and marble slabs. However, suitable sized slabs of other types can also be processed. (Edited author abstract) 4 refs.

**091514 CONTROLLED FRACTURE IN A FINITE GEOMETRY BODY AS A STONE SHAPING TOOL.** A stone cutting technique capable of manufacturing curved shell sections from rectangular stone slabs has been recently proposed. Initially the rectangular slab of stone is prestressed by means of metal stamp pads which are rubber lined to prevent damage to the stone. Knife edges are then applied to the prestressed system at some fixed distance from the pads. As the load on the knives reaches a critical value, the stone fractures underneath the knife edges. The resulting crack propagation is curved and symmetric. Experiments with a limited number of different stones have shown that the initial angle of crack propagation is practically independent of the type of stone being cut. The purpose of this paper is to perform a preliminary analysis of this fracture process and to quantify such values as the initial angle of crack propagation and the critical knife-to-stamp load ratios producing fracture. (Edited author abstract) 6 refs.

**091517 CONCEPTUAL DESIGN AND INTEGRATION OF A SPACE STATION RESISTOJET PROPULSION ASSEMBLY.** The resistojets propulsion module is designed as a simple, long life, low risk system that offers operational flexibility to the Space Station Program. It can dispose of a wide variety of typical Space Station waste fluids by using them as propellants for orbital maintenance. A high-temperature mode offers relatively high specific impulse with long life while a low-temperature mode can propulsively dispose of mixtures that contain oxygen or hydrocarbons without reducing thruster life or generating particulates in the plume. A low-duty cycle and a plume that is confined to a small aft

region minimizes the impacts on the users. Simple interfaces with other Space Station systems facilitate integration. (Edited author abstract)

Tacina, Robert R. (NASA, Cleveland, OH, USA). *NASA Tech Memo* 89847 1987 17p.

**091518 NEW GENERATION OF SPACE ENGINES.** A primary method of launching future spacecraft will be the Space Transportation System (STS). Studies have identified minimum length stages capable of lifting heavy and deployed payloads from the STS low-Earth orbit to geosynchronous Earth orbit using storage or cryogenic propulsion systems. Aerojet TechSystems is presently developing two engines suitable for these stages, a storage engine in the few thousand pound thrust range, and a cryogenic engine with a thrust of only a few hundred pounds. The storage engine breadboard testing has been accomplished, and the flightweight development program will be complete by the end of this decade. A qualified engine is anticipated for service in the early 1990 time frame. The low-thrust cryogenic engine lags this storage engine by approximately three years in development and availability. This paper discusses the technical issues, their solutions, and the development status of these two engines. (Edited author abstract)

**091521 ASSESSMENT OF EXISTING AND FUTURE LAUNCH VEHICLE LIQUID ENGINE DEVELOPMENT.** Existing liquid propellant engines for large launch vehicles are described in terms of pertinent engine and propellant parameters and their launch vehicle application. The development approach and the maturity of engine technology which prevailed prior to and early in specific engine development programs are discussed including lessons learned. New engines, including improved conventional and new concepts that could support the next generation launch vehicle, are delineated with emphasis on technology. The technology maturity and development needed to alleviate the potential development risk are presented along with projected gains in performance, operability, reusability, reliability and producibility. A technology ranking methodology which incorporates a relative transportation system life cycle cost (LCC) as the payoff function is developed. The methodology is useful for establishing preliminary but timely cost effectiveness rankings of various technologies. (Edited author abstract) 5 refs.

## Boosters

**091525 SOVIET TYPE G BOOSTER - A SKEPTICAL VIEW.** This paper examines the available sources of information in an attempt to determine if the Lenin booster ever existed, concentrating on seven aspects of the supposed booster's mission: 1) the mission profile, 2) the Soyuz spacecraft, 3) the Type G engines 4) the Proton booster, 5) the Lunar landing vehicle, 6) the alleged launch date, and 7) the available evidence of the explosion that allegedly occurred upon liftoff of the booster during its first test of July 4, 1969. (Author abstract) 41 refs.

Anderman, D. *J Br Interplanet Soc* v 40 n 5 May 1987 p 223-229.

## Combustion See Also PROPELLANTS—Solid.

**091526 PRESSURE-CONTROLLABLE BURNER.** A modified test burner device called the pressure-controllable burner, based on the conventional T-burner and T-motor, has been constructed for measuring the response function of solid propellant combustion. On this device is mounted a controller system which can modulate the

mean pressure in the burner's chamber according to test needs, and maintain the same pressure level after burnout as before. It can be seen from the test traces that the frequency shifts of acoustic pressure oscillations during the growth period and decay period are slight (less than 5% and 10%, respectively), and the difference between these frequencies is slight. Therefore, the response functions measured by the pressure-controllable burner have higher accuracy and better repeatability as compared with those obtainable from conventional burners. (Edited author abstract) 4 refs. In Chinese.

**091527 NUMERICAL ANALYSIS OF SSME PRE-BURNER INJECTOR ATOMIZATION AND COMBUSTION PROCESSES.** The coaxial spray injection and combustion flowfields of a Space Shuttle Main Engine preburner injector element have been analyzed using a three-phase numerical code, with the objective of defining the flame characteristics and obtaining the temperature profiles at various locations downstream. The former is crucial for delineating the factors that control combustion instability and efficiency, whereas the latter is important for ensuring that temperature nonuniformities are within the design limits as the hot gas enters the turbine nozzles. The model is unique in its comprehensiveness of the physics that are incorporated, which include the processes of atomization, evaporation, secondary droplet breakup, multispecies chemistry, and turbulent diffusion. The model produced realistic results of the complex flowfield, yielding information on the liquid jet length, spray shape, flame zone size and characteristics, and droplet properties. The temperature levels are generally in agreement with the available test data. An external group combustion-type of flame is predicted. Salient combustion and mixture features are discussed, and sources of uncertainty are pointed out for future studies. (Author abstract) 18 refs.

## Combustion Chambers

**091528 ADVANCES IN HIGH CHAMBER PRESSURE PROPULSION.** The space shuttle main engine (SSME), a liquid oxygen, liquid hydrogen-fueled rocket engine capable of 512,000 lbf vacuum thrust represented the solution to system requirements of high performance, reusability, and long life. Solutions that NASA/Marshall Space Flight Center (MSFC) pursued to accomplish the high performance, long life goals set for SSME are discussed. In addition, currently projected requirements for liquid rocket engines have identified liquid oxygen/hydrocarbon-fueled engines for booster application in the near future. These advanced hydrocarbon-fueled engines will require improvements in performance and life to be suitable for their projected missions. Raising chamber pressure to increase performance and reduce engine envelope are the key objectives in hydrocarbon-fueled engine technology. (Edited author abstract)

McCool, Alexander A. (NASA, Huntsville, AL, USA); Richmond, Robert J. *Space Technol (Oxford)* v 7 n 4 1987 p 281-285.

**091529 FLOWFIELD IN A DUAL-INLET SIDE-DUMP COMBUSTOR.** The cold flowfield of a side-dump combustor, which consisted of a plexiglass, circular duct with two 60-deg curved inlets located radially at an angle of 180 deg, is measured quantitatively using laser-Doppler velocimetry. Air was used as a flow medium. The Reynolds number, based on the combustor diameter and bulk velocity, was  $2.6 \times 10^4$ . Detailed profiles of mean velocities and turbulence intensities are reported. The impinging stagnation point of the inlet jets, the lengths needed to reach both one-way flow and fully developed mean-velocity profile, and the primary combustor flow regions are determined. In addition, the homogeneity and isotropy of the turbulence are documented.

Furthermore, the results also identify the part of fluid dynamic characteristics unable to be predicted by two-dimensional models. This information will be useful to test and develop combustor modeling in this area. (Author abstract) 17 refs.

## Control

**091530 RESISTOJET CONTROL AND POWER FOR HIGH FREQUENCY AC BUSES.** Resistojets are operational on many geosynchronous communication satellites which all use dc power buses. Multipropellant resistojets were selected for the Initial Operating Capability (IOC) Space Station which will supply 208 V, 20 kHz power. This paper discusses resistojets heater temperature controllers and passive power regulation methods for ac power systems. A simple passive power regulation method suitable for use with regulated sinusoidal or square wave power was designed and tested using the Space Station multipropellant resistojets. The breadboard delivered 20 kHz power to the resistojets heater. (Edited author abstract) 26 refs.

## Cooling

**091531 UNTERSUCHUNGEN VON FLUESSIGKEITS-FILMSTROMUNGEN BEI HOHEN VERDAMPFUNGSRATEN IM HINBLICK AUF FILMKUEHLUNG.** [Investigation of Annular Flow at High Evaporation Rates with Respect to Liquid Film Cooling]. The process of liquid film cooling of combustion chamber walls subjected to extremely high heat rates is investigated. A theoretical model has been developed for a reliable prediction of the film cooling length. The mass transfer at the liquid-gas interface results from evaporated liquid and entrained liquid droplets. The film cooling length analysis, which includes the physical effects in detail, is separated into two regions: heating the liquid and evaporating the liquid. The theoretical results were experimentally verified at high pressures and temperatures using a modified  $H_2/O_2$ -rocket motor. (Edited author abstract) 71 refs. In German.

## Costs

**091532 LIFE-CYCLE-COST CONSIDERATIONS FOR LAUNCH VEHICLE LIQUID PROPELLANT ROCKET ENGINE.** This paper discusses the engine cost contribution to the life cycle cost of launch vehicles and what cost differences exist between engines designed for expendable and reusable vehicles. The cost drivers in the engine development and production phases, and during vehicle flight operation, are delineated. Analysis of historical cost data and parametric cost modeling were used as a basis for the cost observations. Several measures for potential engine cost reduction are discussed. (Edited author abstract) 11 refs.

## Design See Also SPACE SHUTTLES—Launching.

**091533 DESIGN AND PERFORMANCE TESTS OF A LOW POWER DC ARCJET THRUSTER.** This paper describes a quasi-one-dimensional flow model which can be used for the design of an arcjet thruster. Owing to the simplicity of the model, the performance characteristics of the thruster can be calculated easily to find an optimum configuration suitable for various missions. In order to verify the adequacy of the model, a thruster was fabricated and its performance characteristics were measured. The experimental results were compared with the calculations performed with the model. Both are in satisfactory agreement, and it is concluded that this flow model is a

useful tool for the design of an arcjet thruster. (Edited author abstract) 2 refs.

**091534 DUAL-INTERRUPTED-THRUST PULSE MOTOR.** This paper presents the design and testing of a new pulse motor concept designated dual-interrupted-thrust (DIT). The DIT motor incorporates two tandem propellant grains, separated by an interstage bulkhead having a central opening or port. During operation of the first stage, the port, which is substantially larger than the nozzle throat, is closed by a frangible ceramic cover. At a later time, when the second stage is ignited, the port cover shatters into small harmless fragments and the combustion gases flow without significant pressure losses into the empty first-stage chamber and out the nozzle. Static firings conducted to date indicate that DIT is a viable and attractive pulse motor concept. 4 refs.

**091535 DESIGN METHODS IN SOLID ROCKET MOTORS.** This collection of papers contains 10 papers summarizing the state-of-the-art in designing solid rocket motors and their components. The scope is to collect the experience of several countries in using new technologies and new methods which have been developed over the past ten years. Specifically, the papers deal with propellant grain, motor cases, nozzles, internal thermal inhibitions, and general optimization of solid rocket engines. Six papers are in English, four are in French. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10760 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**091536 ARCJET STARTING RELIABILITY: A MULTISTART TEST ON HYDROGEN/NITROGEN MIXTURES.** An arcjet starting reliability test was performed to investigate one feasibility issue in the use of arcjets on board a satellite for north-south stationkeeping. A 1 kW arcjet was run on hydrogen/nitrogen gas mixtures simulating decomposed hydrazine. A pulse width modulated power supply with an integral high voltage starting pulser was used for arc ignition and steady-state operation. The test was performed in four phases in order to determine if starting characteristics was performed in four phases in order to determine if starting characteristics changed as a result of long term thruster operation. More than 300 successful starts were accumulated over an operating time of 18 hr. Overall results indicate that there is a link between starting characteristics and long term thruster operation. (Edited author abstract) 9 refs.

Haag, Thomas W. (NASA, Cleveland, OH, USA); Curran, Frank M. *NASA Tech Memo* 89867 May 11-13 1987 14p.

**091537 LOW POWER dc ARCJET OPERATION WITH HYDROGEN/NITROGEN/AMMONIA MIXTURES.** An experimental investigation was conducted to determine the effect of gas composition and ambient pressure on arcjet operation. Arcjet operation in different facilities was also compared to determine the validity of tests in small facilities. Volt-ampere characteristics were determined for an arcjet using hydrogen/nitrogen mixtures (simulating both ammonia and hydrazine), hydrogen/nitrogen/ammonia mixtures, and pure ammonia as propellants at various flow rates. The arcjet had a typical performance of 450 sec specific impulse at 1 kW with

hydrogen/nitrogen mixtures. It was determined that the amount of ammonia present in the gas stream had a significant effect on the arcjet volt-ampere characteristics. Also, hydrogen/nitrogen mixtures simulating ammonia gave arc characteristics approximately the same as those of pure ammonia. (Edited author abstract) 21 refs.

Hardy, Terry L. (NASA, Cleveland, OH, USA); Curran, Francis M. *NASA Tech Memo* 89876 1987 24p.

**091538 LOW POWER ARCJET THRUSTER PULSE IGNITION.** An investigation of the pulse ignition characteristics of a 1 kW class arcjet using an inductive energy storage pulse generator integral with a pulse width modulated power converter identified several thruster and pulse generator parameters that influence breakdown voltage including pulse generator rate of voltage rise. This work was conducted with an arcjet tested on hydrogen-nitrogen gas mixtures to simulate fully decomposed hydrazine. Over all ranges of thruster and pulser parameters investigated, the mean breakdown voltages varied from 1.4 to 2.7 kV. Ignition tests at elevated thruster temperatures under certain conditions revealed occasional breakdowns to thruster voltages higher than the power converter output voltage. (Edited author abstract) 15 refs.

**091539 ELECTROMAGNETIC EMISSION EXPERIENCES USING ELECTRIC PROPULSION SYSTEMS - A SURVEY.** As electric propulsion systems become ready to integrate with spacecraft systems, the impact of propulsion system radiated emissions are of significant interest. Radiated emissions from electromagnetic, electrostatic, and electrothermal systems have been characterized and results synopsized from the literature describing 21 space flight programs. Electromagnetic radiated emission results from ground tests and flight experiences are presented with particular attention paid to the performance of spacecraft subsystems and payloads during thruster operations. The impacts to transmission of radio frequency signals through plasma plumes are also reviewed. (Author abstract) 70 refs.

**091540 ARCJET COMPONENT CONDITIONS THROUGH A MULTISTART TEST.** A low-power, dc arcjet thruster was tested for starting reliability using hydrogen-nitrogen mixtures simulating the decomposition products of hydrazine. More than 300 starts were accumulated in phases with extended burn-in periods interlaced. A high degree of flow stabilization was built into the arcjet and the power supply incorporated both rapid current regulation and a high voltage, pulsed starting circuit. A nominal current level of 10 A was maintained throughout the test. Photomicrographs of the cathode tip showed a rapid recession to a steady-state operating geometry. A target of 300 starts was selected, as this represents significantly more than anticipated (150-240), in missions of 10 yr or less duration. Weighings showed no apparent mass loss. Some anode erosion was observed, particularly at the entrance to the constrictor. (Edited author abstract) 18 refs.

**091542 2000-HOUR CYCLIC ENDURANCE TEST OF A LABORATORY MODEL MULTIPROPELLANT RESISTOJET.** This paper presents some results of an effort to demonstrate the technological readiness of a long-life multipropellant resistojet for Space Station auxiliary propulsion. A laboratory model resistojet made from grain-stabilized platinum served as a test bed to evaluate the design characteristics, fabrication methods, and operating strategies for an engineering model multipropellant resistojet developed under contract. The laboratory model thruster was subjected to a 2000-hr, 2400-thermal-cycle endurance test using carbon dioxide propellant. Maximum thruster temperatures were approximately 1400°C. The post-test analyses of the laboratory model thruster included an investigation of component microstructures. (Edited author abstract) 12 refs.

Morren, W. Earl (NASA, Cleveland, OH, USA); Sovey, James S. *NASA Tech Memo* 89854 May 1987 22p.

**091543 LOW-POWER ARCJET CYCLIC LIFTEST.** A cyclic lifetest of a low power dc arcjet thruster using a hydrogen/nitrogen propellant mixture simulating hydrazine is currently in progress. Over 300 hr of operation have been accumulated to date in 2 hr duty cycles at a power level of about 1.15 kw, approximating that available on commercial communications satellites. A burn-in period was carried out before consistent operation was attained. After this period, the arcjet operated in a very stable fashion from cycle to cycle. At the beginning of each cycle, there was a brief starting transient followed by a rapid rise to a steady-state voltage. The steady state voltage increased by about 5 v over the first 95 cycles. After this, it increased by only 1 v through the remainder of the test. Thrust measurements taken before the life test and again after the completion of the 144th cycle showed that both thrust, specific impulse, and arc voltage had increased over this period of operation. (Edited author abstract) 24 refs.

**091545 FAST ACTING VALVE FOR MPD ARCJET.** The article reports on the development of a quasi-steady MPD (Magneto-Plasma-Dynamic) arcjet, which is a typical electric thruster device. Since the quasi-steady MPD arcjet is operated in a pulse mode with a very short time interval between pulses (about 1/1,000 s), it requires a propellant valve having high response characteristics. We have developed a fast acting valve (FAV) as a propellant valve for the MPD arcjet, and found that our FAV is of practical use.

**Exhausts** See Also SPACE SHUTTLES—Launching.

**091546 LANGMUIR PROBE SURVEYS OF AN ARCJET EXHAUST.** Electrostatic (Langmuir) probes of both spherical and cylindrical geometry have been used to obtain electron number density and temperature in the exhaust of a laboratory arcjet. The arcjet thruster operated on nitrogen and hydrogen mixtures to simulate fully decomposed hydrazine in a vacuum environment with background pressures less than 0.05 Pa. The exhaust appears to be only slightly ionized (less than 1 percent) with local plasma potentials near facility ground. The current-voltage characteristics of the probes indicate a Maxwellian temperature distribution. Plume data are presented as a function of arcjet operating conditions and also position in the exhaust. (Author abstract) 20 refs.

Zana, Lynnette M. (NASA, Cleveland, OH, USA). *NASA Tech Memo* 89924 1987 28p.

**091547 EVALUATION OF ROCKET PLUME SIGNATURE UNCERTAINTIES.** In this study, a method is developed that systematically accounts for and evaluates the uncertainties involved in predicting infrared radiation and emitted from aluminized rocket plumes. The approach consists of identifying the important parameters for plume infrared radiation calculations and then perturbing these parameters individually about a set of nominal values to establish their influence on the emitted radiation. Finally, all of the individual uncertainties are combined using an appropriate statistical method to obtain the uncertainty factor for the infrared plume signature. 26 refs.

## Fuel Pumps

**091548 THERMAL FINITE-ELEMENT ANALYSIS OF SPACE SHUTTLE MAIN ENGINE TURBINE BLADE.** Finite-element, transient heat transfer analyses were performed for the first-stage blades of the space shuttle main engine (SSME) high-pressure fuel turbopump. Heat transfer coefficients were predicted by performing a boundary-layer analysis at steady-state conditions with the STAN5 boundary-layer code. Two different peak-temperature overshoots were evaluated for the startup transient. Cutoff transient conditions were also analyzed. A reduced gas temperature profile based on actual thermocouple data was also considered. Transient heat transfer analyses were conducted with the MARC finite-element computer code. (Edited author abstract) 11 refs.

## Heat Transfer

**091549 ROTATION EFFECTS ON INHOMOGENEOUS MIXING IN AXISYMMETRIC SUDDEN-EXPANSION FLOWS.** Rotation effects on variable-density co-axial jet mixing in an axisymmetric sudden-expansion geometry are investigated experimentally. A central air jet surrounded by an annular helium/air jet is injected into a circular tube with an enlarged cross-sectional area. Two cases are examined in detail; one stationary and another with a constant speed of rotation of 840 r.p.m. about the tube axis. Results show that mixing between helium and air is greatly enhanced by rotation. (Edited author abstract) 15 refs.

**Ignition** See Also PROPELLANTS—Combustion.

**091550 NUMERICAL MODEL FOR PELLET-DISPERSION IGNITER SYSTEMS.** A fairly comprehensive practical numerical method for the description of ignition transient flow behavior of pellet-dispersion igniter

systems is presented. The model was specifically developed for the study of conventional bag and cartridge igniters employed for small-diameter, composite-propellant rocket motors, but the model in its general form may be adapted for the study of a multitude of ignition transient problems. An extensively modified algorithm based on the random-choice method is applied to obtain the solution of the one-dimensional hydrodynamic equations governing the two-phase core flow behavior within the motor chamber and nozzle, in conjunction with pressure-dependent and crossflow-dependent burning rate equations for the solid propellant and igniter pellets. Good agreement is obtained between experimental firing data and predictions from the model for head-end pressure-time profiles. (Author abstract) 16 refs.

**091551 EXPLOSIVE PLASMA INJECTORS IN THE STUDY OF CIRCUMTERRESTRIAL SPACE.** Among current active experiments performed in space, important results have been obtained with the help of experiments involving the injection of different chemical substances. Experiments with injection are employed for tracing chemical or physical processes, enabling diagnostics of the natural state of the space medium. With the help of injection it is possible to create a disturbance in the medium and to stimulate natural or artificial processes of a geophysical character. 29 refs.

Ruzhin, Yu.Ya.; Skomarovskii, V.S.; Stadnichenko, I.A.; Titov, V.M.; Shvetsov, G.A. *Combust Explos Shock Waves* v 23 n 3 May-Jun 1987 p 350-357.

**091552 HIGH POWER ION THRUSTER PERFORMANCE.** The ion thruster is one of several forms of space electric propulsion being considered for use on future SP-100-based missions. One possible major mission ground rule is the use of a single Space Shuttle launch. Thus, the mass in orbit at the reactor activation altitude would be limited by the Shuttle mass constraints. When the spacecraft subsystem masses are subtracted from this 'available mass' limit, a maximum propellant mass may be calculated. Knowing the characteristics of each type of electric thruster allows maximum values of total impulse, mission velocity increment, and thrusting time to be calculated. Because ion thrusters easily operate at high values of efficiency (60 to 70 percent) and specific impulse (3000 to 5000 sec), they can impart large values of total impulse to a spacecraft. (Edited author abstract) 24 refs.

## Manufacture

**091553 PIONEERING COMMERCIAL ROCK-ETRY IN THE UNITED STATES OF AMERICA: THIOKOL'S REACTION MOTORS DIVISION, 1958-1972, PART 3: RMD OPERATIONAL HISTORY.** This article is the continuation of the history of Reaction Motors. Parts 1 and 2 on Reaction Motors, Inc. appeared in the December 1983 and April 1985 issues of this journal, and covered the corporate and project history of the firm up to its merger with the Thiokol Chemical Corporation at midnight, 30 April 1958. Here in Part 3, we trace the operational history of the Reaction Motors Division within Thiokol's Aerospace Group from May 1958 to the demise of the Division 14 years later. (Author abstract) 7 refs.

Ordway, Frederick I. III (Reaction Motors Inc). *J Br Interplanet Soc* v 40 n 9 Sep 1987 p 389-404.

**091554 PIONEERING COMMERCIAL ROCK-ETRY IN THE UNITED STATES OF AMERICA: THIOL'S REACTION MOTORS DIVISION, 1958-1972. PART 4: RMD PROJECT HISTORY.** This article concludes the history of Reaction Motors. Part 3 dealt with the administrative history of Reaction Motors Division of the Thiokol Chemical Corp. and summarized major and minor projects undertaken during the life of the Division, from 1958 to 1972. This concluding part focuses upon the major projects in more detail. These are the Sparrow III, Bullpup, Corvus, Condor, X-15 powerplant, XLR-II engines in Lifting Bodies, and the Surveyor verner, TD-339. (Author abstract) 55 refs.

Winter, Frank H. (Smithsonian Inst, Washington, DC, USA). *J Br Interplanet Soc* v 40 n 9 Sep 1987 p 405-416.

**091555 ENGINE PRODUCTION SOARS WITH BLEND OF CAD/CAM & ROBOTICS.** The article discusses how programming and simulating robots with CAD/CAM streamlines Space Shuttle engine production. Since 1983, NASA and the Rocketdyne Div., Rockwell International have applied robotic technology to produce the Space Shuttle Main Engines (SSME). At the Productivity Enhancement Facility at Marshall Space Flight Center (MSFC), Huntsville, Ala., engineers develop automated welding processes and tooling for robotic work-cells. The engines are produced and assembled at the Rocketdyne production facility in Canoga Park, Calif. A technology transfer program provides a structured communication link between the two centers.

## Materials

**091556 ULTRASONIC NDE OF STRUCTURAL CERAMICS FOR POWER AND PROPULSION SYSTEMS.** A review is presented on research investigations of several ultrasonic evaluation techniques applicable to structural ceramics for advanced heat engines. This review highlights recent work conducted under the sponsorship of and at the Lewis Research Center. Results obtained with scanning acoustic microscopy, scanning laser acoustic microscopy, photo-acoustic microscopy, and scanning electron acoustic microscopy are compared. In addition to these flaw imaging techniques, microstructure characterization by analytical ultrasonics is described. The techniques were evaluated by application to research samples of monolithic silicon nitride and silicon carbide in the form of discs and bars containing naturally occurring and deliberately-introduced flaws and microstructural anomalies. Strengths and limitations of the techniques are discussed. (Author abstract) 13 refs.

Vary, Alex (NASA, Cleveland, OH, USA); Generazio, Edward R.; Roth, Don J.; Baaklini, George Y. *NASA Tech Memo* 100147 1987 11p.

## Mathematical Models

**091557 STUDY OF COMBUSTION AND FLOW BEHAVIOR IN SOLID-PROPELLANT ROCKET MOTORS.** A comprehensive study of several important aspects of the internal ballistics of solid-propellant rocket motors (SRMs) has been undertaken. Numerical models have been developed for the solution of the quasi-steady and unsteady, one-dimensional, hydrodynamic equations of motion governing the two-phase core flow behavior within the motor chamber and nozzle. A new phenomenological model of erosive burning has been developed and incorporated into an overall solid-propellant combustion model, which in turn is solved in conjunction with the equations of motion for the SRM. The quasi-steady internal ballistics predictions based on the phenomenological combustion model are consistent with experimental observation. In concurrence with the quasi-steady flow analysis, a new phenomenological model was also developed for the description of normal acceleration effects on the combustion process, for the parametric study of spinning, composite-propellant SRMs. (Edited author abstract) 15 refs.

Greatrix, D.R. (Univ of Toronto, Can). *UTIAS Rep* 20 Dec 1987 var pagings.

**091558 TWO-DIMENSIONAL MODEL OF THE PLASMA THRUSTER.** Given the condition that the flow generated by a self-induced magnetic field is two-dimensional and steady, a model for the arc region of the plasma thruster is formulated based on magnetohydrodynamic (MHD) descriptions. Use is made of a generalized Ohm's law that includes the Hall and ion slip terms. Characteristics of the arc region are investigated as functions of system parameters. The study shows that the Hall effect causes the current to concentrate severely at the trailing edge of the anode, and it is suggested that if the plasma thruster is a coaxial type, it is better to have the cathode inside. (Author abstract) 7 refs.

## Nondestructive Examination

**091559 DYNAMIC REAL-TIME RADIOGRAPHY OF SOLID-PROPELLANT ROCKET MOTORS DURING STATIC FIRING.** A radiographic testing setup that allows better understanding of internal-component behavior of solid-propellant rocket motors during static firing has been developed by the Naval Weapons Center (NWC), China Lake, CA. The radiographic systems used are rugged and capable of withstanding rocket motor malfunctions, usually with little or no damage. The testing method, used for both high-energy and low-energy systems, offers several benefits: reasonable cost, probability, protection of equipment, and valuable data. This paper discusses the radiographic systems in use at NWC by describing their capabilities and the functions of their various components and outlines the safety considerations in using each system. High-energy as well as low-energy systems and applications are discussed. (Author abstract) 2 refs.

Rogerson, D.J. *Mater Eval* v 45 n 11 Nov 1987 p 1330-1333.

## Nozzles See Also FLOW OF FLUIDS—Nozzles; HEAT TRANSFER—Nozzles.

**091560 EXPERIMENTAL STUDY OF LOW REYNOLDS NUMBER NOZZLES.** High-performance electrothermal thrusters operate in a low nozzle-throat Reynolds number regime. Under these conditions, the flow boundary layer occupies a large volume inside the nozzle, contributing to large viscous losses. Four nozzles (a conical, bell, trumpet, and modified trumpet) and a sharp-edged orifice were evaluated over a Reynolds number range of 500 to 9000 with unheated nitrogen and hydrogen. The nozzles showed significant decreases in specific impulse efficiency with decreasing Reynolds number. At Reynolds numbers less than 1000, all four nozzles were probably filled with a large boundary layer. The discharge coefficient decreased with Reynolds number in the same manner as the specific impulse efficiency. The bell and modified trumpet nozzles had discharge coefficients 4 to 8 percent higher than those of the cone or trumpet nozzles. (Edited author abstract) 14 refs.

**091561 COMPARISON OF TWO PROCEDURES FOR PREDICTING ROCKET ENGINE NOZZLE PERFORMANCE.** Two nozzle performance prediction procedures which are based on the standardized JANAF methodology are presented and compared for four rocket engine nozzles. The first procedure required operator intercedence to transfer data between the individual performance programs. The second procedure is more automated in that all necessary programs are collected into a single computer code, thereby eliminating the need for data reformatting. Results from both procedures show similar trends but quantitative differences. Agreement was best in the predictions of specific impulse and local skin

friction coefficient. Other compared quantities include characteristic velocity, thrust coefficient, thrust decrement, boundary layer displacement thickness, momentum thickness, and heat loss rate to the wall. (Edited author abstract) 8 refs.

Davidian, Kenneth J. (NASA, Lewis Research Cent, Cleveland, OH, USA). *NASA Tech Memo* 89814 1987 14p.

**091562 DETAILED DESCRIPTION OF THE UNCERTAINTY ANALYSIS FOR HIGH AREA RATIO ROCKET NOZZLE TESTS AT THE NASA LEWIS RESEARCH CENTER.** A preliminary uncertainty analysis has been performed for the High Area Ratio Rocket Nozzle test program which took place at an altitude test capsule. Results from the study establish the uncertainty of measured and calculated parameters required for the calculation of rocket engine specific impulse. A generalized description of the uncertainty methodology employed is provided. Specific equations used and a detailed description of the analysis are presented. Verification of the uncertainty analysis model was performed by comparison with results from the experimental program's data reduction code. (Edited author abstract) 30 refs.

**091563 PERFORMANCE OF HIGH-AREA-RATIO NOZZLE FOR A SMALL ROCKET THRUSTER.** Theoretical estimates of supersonic nozzle performance were compared to experimental test data on nozzles with area ratios of 100:1 (conical) and 300:1 (optimum contour) and on 300:1 nozzles cut off at 200:1 and 100:1. These tests were performed on a 5 lbf monopropellant hydrazine thruster with chamber pressures of 25-135 psia. The analytic method used was the conventional inviscid method of characteristic with a correction for laminar boundary-layer displacement and drag. (Edited author abstract) 4 refs.

## Nuclear Energy See Also SPACECRAFT—Interplanetary.

**091564 STUDY OF SCHWARZ CONVERTERS FOR NUCLEAR POWERED SPACECRAFT.** High power space systems which use low dc voltage, high current sources such as thermoelectric generators, will most likely require high voltage conversion for transmission purposes. This study considers the use of the Schwarz resonant converter for use as the basic building block to accomplish this low-to-high voltage conversion for either a dc or an ac spacecraft bus. The Schwarz converter has the important assets of both inherent fault tolerance and resonant operation and parallel operation in modular form is possible. A regulated dc spacecraft bus requires only a single stage converter while a constant frequency ac bus requires a cascaded Schwarz converter configuration. If the power system requires constant output power from the dc generator, then a second converter is required to route unneeded power to a ballast load. (Author abstract) 15 refs.

**091566 NUCLEAR FERRY - Cislunar Space Transportation Option of the Future.** This paper summarizes the results of a study concerning the use of solid Core Nuclear Rocket Engines in future commercial space transportation systems. Tungsten-water moderated reactors were chosen to be the most desirable reactor type due to high specific impulse, lowest weight and longest life time. A Life Cycle Cost analysis for a 50 year life-time demonstrated that nearly 50% of the total LCC are consumed by Earth-to-LEO transportation cost. Orbital burden cost due to ferry maintenance and repair were found to be the second important cost driving factor. Increased vehicle size reduced the specific transportation cost only slightly while smaller vehicles increase cost significantly. (Author abstract) 9 refs.

**091569 DIRECT MEASUREMENT OF HIGH FREQUENCY, SOLID PROPELLANT, PRESSURE-COUPLED ADMITTANCES.** This paper presents an experimental method that is capable of directly measuring solid propellant pressure-coupled responses at the high frequencies associated with tangential mode instabilities inside solid propellant rocket motors. The method utilizes a magnetic flowmeter to measure the velocity oscillation above a burning propellant surface simultaneously with a pressure oscillation measurement within an externally excited combustion chamber. A magnetic flowmeter burner was designed and constructed to evaluate this method of pressure-coupled response measurement. Response measurements were obtained for two formulations of AP/HTPB composite propellant at pressure oscillation frequencies of 4000 and 8000 Hz. The measurement data

displayed repeatable trends in both the real and imaginary parts of the pressure-coupled response function. (Author abstract) 8 refs.

## Pumps

**091570 EXPERIMENTAL STUDY ON HIGH-PRESSURE GAS SEALS FOR A LIQUID OXYGEN TURBOPUMP.** An experimental study on high-pressure gas seals was carried out in order to investigate the feasibility of a liquid oxygen (LOX) turbopump rotating-shaft seal system for Japan's LE-7 rocket engine. Floating-ring seals 50 millimeters in diameter were successfully operated under the following conditions: a maximum rotational speed of 25,000 rpm and a maximum sealed hydrogen gas pressure of about 15 MPa. The leakage rates obtained in the experiment were in good agreement with analytical results obtained from a quasi-one-dimensional compressible flow equation. A 100-millimeter-diameter double segmented hydrodynamic circumferential seal designed for a helium gas purge system was tested in order to investigate the wear process of the carbon segmented-rings. The seal was operated for about 1.5h under the following conditions: a helium purged-gas pressure of about 0.6 MPa and a rotational speed of about 20,000 rpm. Under these conditions rubbing contact between the carbon segmented-rings and the runner occurred; however, the wear rates of carbon segmented-rings decreased with time and the maximum wear depth was less than 10µm after this test. (Edited author abstract) 5 refs.

## Stability

**091574 ACOUSTIC MODE DETERMINATION IN SOLID ROCKET MOTOR STABILITY ANALYSIS.** It is the purpose of this work to show that the classical rigid-wall assumption used to evaluate the chamber acoustic modes does not ensure the independence of the stability integrals from the location of the aft closure plane. This point is particularly crucial when the nozzle length is not small compared to the motor length. A simple acoustic admittance boundary condition will be proposed that greatly improves the stability analyses through an improved reference acoustic mode determination. 8 refs.

**091577 LIFE TEST OF A 22-NEWTON (5-LBF) HYDRAZINE ROCKET.** Life tests were conducted on a 22-N (5-lb) hydrazine rocket thruster which incorporates the latest technology to obtain long life from the catalyst bed. A spring mechanism surrounding the catalyst bed continually applies compression to the catalyst bed to prevent the formation of any void channels. The thruster was tested over an operational cycle of both steady-state and pulse firing which simulated a possible Space Station duty cycle. It ran as expected for about 40 hr, or  $3.2 \times 10^6$  N-sec ( $7.2 \times 10^5$  lb-sec) total impulse. Subsequently, some thrust chamber pressure decreases were noted during long steady-state test periods. After 60.2 hr of run time, the tests had to be terminated due to a blockage in the propellant injector tube which occurred during heating of the thruster by a heat lamp. The thruster had accrued over  $4.8 \times 10^6$  N-sec ( $1.1 \times 10^6$  lb-sec) of total impulse before

the injector tube was inadvertently blocked. After disassembly and inspection of the thruster, a chemical analysis of the catalyst indicated that iron and nickel metals had poisoned some of the catalyst, thereby causing a degradation in performance. (Edited author abstract) 5 refs.

## Thermoanalysis

**091580 TWO-DIMENSIONAL FINITE DIFFERENCE PROGRAM FOR THERMAL ANALYSIS OF ROCKET THRUST CHAMBERS.** A two-dimensional finite difference computer model for thermal analysis of rocket thrust chambers has been developed. The model uses an iterative scheme for calculating the temperature distribution within the chamber wall and implements a successive overrelaxation formula for a quick convergence. The inputs of the model are the dimensions of the thrust chamber wall, types of materials used, heat transfer coefficients and temperatures of the hot gas and the coolant. The resulting output of the program consists of the nodal temperature distribution, heat transfer to the coolant, and heat transfer from the hot gas. (Author abstract)

**091581 ON THE RELATIVISTIC THEORY OF ROCKET FLIGHT.** It is shown by macroscopic analysis that, when the entire mass of a rocket is consumed for creating thrust, objects may be obtained as a result having energy but zero mass, moving the velocity of light. It is shown that the boost process of such massless objects can be realized in finite time from the observer's point of view. The vast stellar luminosity of quasars and certain jet motions observed in remote space can be explained by the production of massless radiation with internal motions connected with the separation of large energies inside the stars. **091583 COMPUTATION ON SHOCK STRUCTURES OF THE ROCKET EXHAUST PLUMES.** The physical solution of the initial and boundary problems of the rocket and missile impingement with complex shock structures in arbitrary bounded flow fields has been calculated in this paper. The formulae of Godunov's scheme on irregular grid are derived here. A body-fitted coordinates network constructed by using Thompson's Method is applied in our calculation. Some results of the interactions of the rocket exhaust plumes and strong impingement solved in second class grid have also been given. (Author abstract) 6 refs. In Chinese.

Zhang, Fuxiang; Lian, Wenyu. *Bingong Xuebao* n 2 May 1988 p 9-16.

## Accident Prevention

**091584 LABORATORY SHIELDING FOR PROJECTILES.** This paper addresses the considerations for containing missiles with different types of shielding; the blast resistance of shielding is not discussed. Missile hazards are often accompanied by blast waves. Rigid walls of steel or reinforced concrete are usually needed for blast resistance. However, if a shield is to be designed to withstand both blast and missiles, the thickness required to stop the missiles will almost always be adequate to absorb the blast wave. Preliminary cost estimates, therefore, need be based only on consideration of missiles. For detailed design, the services of a competent structural engineer with dynamic design experience are required to ensure that the supports for the walls are adequate for any blast forces. 8 refs.

**091586 VORTEX FILAMENT MODEL OF THE WAKE BEHIND A MISSILE AT HIGH ANGLE OF**

**ATTACK.** A method for calculation of the flow past a missile at high angle of attack is described in which the vortex wake is approximated by means of three-dimensional vortex filaments attached to given open separation lines. The condition of tangential flow on the body is satisfied by use of quadrilateral source panels. Each filament consists of straight-line segments, ending in a semi-infinite segment parallel to the freestream, and is made part of a system of vortices of horseshoe type by means of connecting segments inside the body. The method involves the simultaneous calculation of the rollup and circulations of the vortex filaments, using conditions that hold along the juncture of a separating vortex sheet and the body. Calculations are presented for a blunted ogive cylinder at 10-deg incidence and for a hemisphere cylinder at 19-deg incidence, starting from separation lines obtained by use of the thin-layer Navier-Stokes equations. (Author abstract) 22 refs.

**091587 COMPUTER AIDED AERODYNAMIC DESIGN OF MISSILE CONFIGURATION.** Aerodynamic configurations of tactical missiles have to produce the required lateral force with minimum time lag to meet the required maneuverability and response time. The present design which is mainly based on linearized potential flow involves (a) identification of critical design points, (b) design of lifting components and their integration with mutual interference, (c) evaluation of aerodynamic characteristics, (d) checking its adequacy at other points, (e) optimization of parameters and selection of configuration, and (f) detailed evaluation including aerodynamic pressure distribution. Iterative design process is involved because of the mutual dependence between aerodynamic characteristics and the parameters of the configuration. (Edited author abstract) 5 refs.

## Control

**091589 EFFECT OF GIMBAL FRICTION MODELING TECHNIQUE ON CONTROL STABILITY AND PERFORMANCE FOR CENTAUR UPPER STAGE.** The powered-phase autopilot for the Centaur upper stage rocket uses an autopilot forward loop gain scheduler that decreases the proportional gain as propellant mass is depleted. Nonlinear time response simulation studies revealed that Centaur vehicles with low-gain autopilots would have large attitude error limit cycles. These limit cycles were due to the assumed presence of Coulomb friction in the engine gimbals. This situation could be corrected through the use of an harmonic 'dither,' programmed into the on-board digital computer and added to the engine command signal. Control authority was found to be restored when dither was used. It is recommended that autopilot simulation studies for future Centaur vehicles include a bend and slide engine gimbal friction

model, with a small amount of Coulomb friction, modeled as part of the actuator dynamics, for a conservative stability analysis. (Edited author abstract) 10 refs.

## Costs

**091591 MISSILE PROPULSION COST MODELING.** An approach for parametric propulsion system cost modeling is presented and is illustrated by Cost Estimating Relationships (CERs) for unit production costs of solid propellant booster stages. Due to their relative simplicity, the costs obtained from the CERs represent only first order approximations of booster stage costs. They were developed from cost and technical data of historical propulsion systems available in the open literature. The approach for developing the CERs is outlined and the rationale for the selection of independent parameters is presented. The analysis of the cost data revealed several generic observations and rules of thumb. These are given since they might prove useful for back of the envelope type cost predictions. (Edited author abstract). 2 Refs.

**091595 OPTIMAL INTERCEPT GUIDANCE LAW WITH UNCERTAINTY FACTORS AND NORMAL CONSTRAINT.** From the point of view of a differential game, an optimal intercept guidance law with uncertainty factors and normal constraint is discussed using minimum-maximum principle. It is assumed that the kinetic characteristics of the guided object is a first order lag loop; the minimum control energy consumption is taken as the performance index; the terminal states belong to an intercept curved surface with out-off control and the terminal acceleration of the guided object equals zero; the force controlling the guided object satisfies the normal constraint and the maneuver of the target is considered as the uncertainty factor. The author has deduced an optimal intercept guidance law in a closed loop analytical form for the case where the change of direction of motion of the guided object is not large. (Edited author abstract) In Chinese. 7 refs.

Zhan, Zhixiang. *Xibei Gongye Daxue Xuebao* v 5 n 4 Oct 1987 p 447-456.

**091596 INTEGRATION OF GPS/INS FOR MAXIMUM VELOCITY ACCURACY.** It is shown that weapon delivery accuracy using GPS depends more on velocity accuracy than position accuracy if jamming occurs several minutes before reaching the target. The total accuracy deteriorates very slowly the first few minutes after jamming provided the GPS and INS are integrated for maximum velocity accuracy. Also, rate-aiding of the carrier loop with INS data is shown to be practical provided proper attention is paid to attitude motion compensation, and compensation for lags in INS data as small as a millisecond. (Author abstract) 19 refs.

Diesel, John W. (Diesel Computing Systems Inc, Woodland Hills, CA, USA). *Navigation* v 34 n 3 Fall 1987 p 190-211.

**091597 CAN A MIXED GUIDANCE STRATEGY IMPROVE MISSILE PERFORMANCE?** The terminal phase of a missile vs aircraft engagement in an uncertain, noise-corrupted environment is formulated as a partial-information differential game. The cost function of the game is the missile's single-shot kill probability. A new approach, allowing a mixed missile guidance strategy, leads to a feasible saddle-point solution and circumvents the difficulties encountered in previous investigations. A simple example demonstrates that in some cases, the implementation of optimal mixed strategies is indeed advantageous for both parties. The present paper is the first step in the search for feasible saddle-point solutions for a large class of nondeterministic pursuit-evasion games. (Author abstract) 31 refs.

**091598 DESIGN OF ADAPTIVE AUTOPILOT FOR TACTICAL MISSILES.** This paper studies the possibility of designing digital adaptive autopilot of tactical missiles, using model reference adaptive control

(MRAC) with explicit identification. The plant considered is the roll loop of the air-to-air missiles whose dynamic parameters vary within wide limits. The recursive least square (RLS) method, with a forgetting factor for the second order plant, is selected to implement the on-line parameter identification, and a P+I adaptive law is used to make the plant output follow the reference model output very closely. All the differential equations are transformed into different equations using backward difference method in order to avoid the trouble caused by the inherent one-step sampling lag. Some practical problems encountered in design are discussed. The parameter identifications for two kinds of inputs are given. It is shown that the results of using MRAC with real-time identification are in agreement with those using MRAC with real values of the plant parameters. (Edited author abstract) In Chinese. 6 refs.

**091599 DESIGN AND SIMULATION OF AN ADAPTIVE CONTROL SYSTEM FOR A LASER BEAM-RIDER GUIDED TRIAL-MISSILE.** In this paper, we use discrete model reference adaptive control approach to design and analyze a laser beam-rider guided trial-missile control system. When the signal magnitude is limited through the use of a limiter, a great loss of the system performance is usually incurred. But the proposed approach can assure that the system retains satisfactory performance as long as the limiting factor is selected properly. (Edited author abstract) In Chinese. 7 refs.

**091600 INERTIAL GUIDANCE SYSTEM FOR THE H-I LAUNCH VEHICLE - NICE.** This report describes an outline of the NICE (NASDA Inertial-guidance and Control Equipment) inertial guidance system developed for the NASDA H-I launch vehicle. MHI has participated in NICE system integration support, the development of the flight program and the data interface unit. This system provides for first and second stage attitude control, navigation and guidance, second stage tank pressurization control, and vehicle sequencing functions. The functions and performance of the NICE system were perfectly certified through the first flight of the H-I launch vehicle (Test flight #1 mission) on August 13, 1986.

**091601 TESTING ICBM TRANSPORTATION PAD SEPARATION.** During horizontal transport and handling, a small ICBM is protected within the erection and firing canister by some 80 molded urethane/aluminum composite pads arranged in 10 circumferential rows at key locations along the missile's length. Each row of pads is secured to the missile by two tension cables and toggle latches. Every cable includes a tensioning device and a tension-load indicator to facilitate installation and routine inspection. At launch, each row of pads with its retaining cables must remain in place on the missile as the assembly moves upward within the canister while passing over a variety of irregularities in the canister wall. Upon exiting the mouth of the canister, each row of pads must automatically separate from the missile and fall clear. To demonstrate that the required pad separation will occur promptly, but not prematurely, a low-cost simulation test was devised that required neither a missile nor a canister.

**091605 HIGH PERFORMANCE MISSILE SYNTHESIS WITH TRAJECTORY AND PROPULSION SYSTEM OPTIMIZATION.** Synthesis of a high-performance two-pulse-motor-propelled missile by simultaneous optimization of trajectory and propulsion systems in two operational scenarios is described. This work employed a quasi-Newton parameter optimization scheme with penalty functions to meet terminal and path constraints. The trajectory control variables were parameterized using piecewise linear open-loop commands and piecewise constant linear feedback gains. The pulse motor parameters optimized were pulse split, average thrust levels, neutrality factors, pulse burn times, and the interpulse delay. Optimization of the rocket motor thrust curve in addition to the trajectory increased the range by up to 11% when compared with the trajectories optimized with originally specified rocket motor propulsion data. (Author abstract) 16 refs.

**091606 ANALYTICAL SOLUTIONS TO ROCKET PERFORMANCE WITH AN ARBITRARY THRUST PROGRAMME HAVING CONSTANT THRUST INCLINATION WITH RESPECT TO THE HORIZON IN VACUUM.** The investigations described in this paper pertain to rocket performance due to maneuvering in a

vacuum with an arbitrary thrust inclined at a constant angle with respect to the horizon. Considering the variable thrust either as a function of time, or mass ratio, it is established that dynamical equations projected on the horizontal and vertical directions can be solved analytically; closed-form solutions to the overall range, endurance and final or impact velocity arising out of both burning and coasting phases can be achieved depending on the nature of the thrust function. Rocket performance with an arbitrary thrust program of greater thrust function evolves greater peak altitude for a vertical path, and greater overall but shorter burnout range, for the curvilinear path. (Edited author abstract). 2 Refs.

**091608 ANALYSIS ON THE IMPULSE LOSS OF SOLID-PROPELLANT ROCKET ENGINES.** Under the condition of  $V_p/LF$  1.0, an equilibrium model is used to study the specific impulse loss in solid propellant rocket engines. Some equations of rocket nozzle properties, including the critical velocity and specific impulse, are derived. The calculated results show that the velocity at the throat of the nozzle is less than the sonic speed of the gas, and the specific impulse is lost due to the effects of solid particles. The thrust coefficient does not always decrease, and it depends on the expansion ratio and solid mass ratio. A computer program TWPH is completed. The results of computation are compared with the experimental results of Winston N. Brundige giving satisfactory coincidence. (Edited author abstract) 6 refs. In Chinese.

**091609 FIXED-RANGE OPTIMAL RE-ENTRY MANEUVERS WITH BOUNDED LIFT CONTROL.** Optimal lift control for transferring a hypervelocity vehicle between fixed initial and final values of the range and flight-path angle, with a maximum bound imposed on the magnitude of the lift coefficient, is derived using Green's theorem. payoffs are either maximum final velocity, maximum final altitude, minimum time, or minimum heat input. It is shown that the optimal maneuver for either payoff consists of a max. lift/min. lift or min. lift/max. lift nonsingular path and conditions for the final state to be reachable by such a sequence are determined. Only descending or ascending trajectories are considered, for which analytical solutions are obtained and the location of switching points determined. Results of parametric studies are presented in nondimensional form. (Author abstract) 5 refs.

**091610 THERMOPHYSICAL ASPECTS OF RE-ENTRY FLOWS (TECHNICAL PAPERS SE-**

**LECTED FROM THE AIAA 23RD AEROSPACE SCIENCES MEETING AND THE AIAA 20TH THERMOPHYSICS CONFERENCE).** This conference proceedings contains 24 papers. The emphasis of the conference is on research and development activities on re-entry flows. Various chapters are introduced covering: Low-density phenomena; high temperature kinetics and transport properties; aerothermodynamic ground simulations and measurements; and numerical simulations of hypersonic flows. Much of the motivation for the research concerning the thermochemical state of high temperature shock-layer gases is to enhance the capability to predict the radiative heating environment for aerossisted orbital transfer vehicle (AOTV) entry conditions. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 11446 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

## Reviews

**091611 TECHNOLOGY '88: AEROSPACE AND MILITARY.** This overview of 1987 developments focuses on missiles, which overshadowed other events. The discussion covers the performance of Cruise missiles; the development of radar-triggered missiles; and the accuracy of the US Trident II missile. Also considered are the B-1B bomber and antimissile plans for the US Strategic Defense Initiative. An expert opinion is offered by Thomas F. Curry, chief scientist at E-Systems' center for advanced planning and analysis, who discusses belt-tightening by the US Department of Defense.

## Welding

**091612 AUTOMATSKO ZAVARIVANJE KOMORE RAKETNIH MOTORA TIG POSTUPKOM BEZ I SA DODATKOM MATERIJALA.** [Automated TIG welding with and without Filler Material of a Missile Motor]. The requirements of the designers for an increased reliability of weldments, high mechanical properties of the welded joint, almost at the level of the base material, making of welded joint without defects, an increased material thickness and selection of steels prone to welding cracks, have resulted in a particular interest of the process engineers in the application of the optimum welding procedure in order to achieve the stated requirements. In cases of very critical weldments which involved fabrication in heavy and complicated tools, the investigation was directed to the application of automated production by using TIG procedure in two passes: with and without filler material. This paper also presents the results of all the accompanying tests of welded joints which are essential with such rigid design requirements. (Author abstract) In Serbo-Croatian. 9 refs.

**091614 NEW DEVELOPMENTS IN ROD MILLS. PART I - DESIGN AND OPERATION.** Compact rolling mills have been developed for high-precision production of wire rod. Advantages include: twist-free rolling in single, 3-roll stands; quick C changing of stands; minimum temperature variation during rolling; and high yield and utilization. A finishing block produces 5.5 to 12.5-mm dia specialty steel rod to within a normal and specially controlled dimensional tolerance of  $\pm 0.15$  and  $\pm 0.08$  mm, respectively.

Blos, Ernst O. (Friedrich Kocks GmbH, Hilden, West Ger). *Iron Steel Eng* v 63 n 12 Dec 1986 p 35-41.

**091615 NEW DEVELOPMENTS IN ROD MILLS. PART II - OPERATION OF A SPECIALTY STEEL WIRE ROD FINISHING MILL AT TOYAMA WORKS.** In 1983 Nippon Koshu Steel Co., Ltd. (NKS) installed a new high-performance finishing mill for rolling high-alloy wire rod at the Toyama works. The goals were to obtain higher productivity and improved quality. This mill, a 3-roll block mill designed and built by Kocks, was selected for rolling the entire NKS product mix (bearing, tool and die, high-speed, carbon, valve, stainless, heat-resistant and other specialty steels and super alloys) in many sizes and in small lots at maximum efficiency. This article describes the new mill and its performance during the first 30 months of operation.

**091616 BASIC RESEARCH ON THE PROCESS OF COMPONENTS-ROLLING (5TH REPORT, OPTIMIZATION OF THE PROCESS BY MEANS OF CHANGING THE CHARACTERISTICS AND ADJUSTABLE ROLLING PARAMETERS OF A ROLLING MACHINE).** The forming process in components-rolling is governed by many factors relating to deformation and the rolling machine. In order to provide a fundamental approach to the optimization of the process by means of changing the characteristics inherent in each rolling machine and controlling the adjustable rolling parameters, a series of theoretical simulations was carried out. A new method of simulation of the process based on an equivalent configuration model is proposed to obtain detailed information without tedious calculation. Theoretical simulation is done by changing the elastic characteristics of a machine, upper preset load, the penetration rate of die and the preset position of a die-stopper, and the preferable rolling condition becomes clear. On the basis of these analyses, design and controlling principles of machines for improving the accuracy of form are pointed out for the first time. (Author abstract) In Japanese. 6 refs.

**091617 HEATING AND ROLLING OF LIQUID-CORED 'ZF' INGOTS.** The 'ZF' process is a new process to team rimmed steel which has been investigated and developed jointly by Anshan Institute of Iron and Steel Technology and Anshan Iron and Steel Corporation.

In this paper, the deformation characteristics of the liquid core rolling of ZF 6.67t rimmed steel ingots, the percentage available for liquid core rolling and the solidification curve of the ingots were thoroughly studied by simulation in the laboratory and in situ. A new production technology has been worked out in accordance with the characteristics of the ingots which makes the average charging temperature of ZF6.67t rimmed steel ingots reach 1006.2°C, and the percentage of liquid core heating reach 82.58%, so that the capacity of the soaking pit is increased by 1/3, the iron loss during heating is decreased by 0.7%, and 46.5% of the gas is saved. It is proved that the 'ZF' process is an efficient measure ensuring liquid core heating and rolling. (Edited author abstract) In Chinese.

**091618 SOFTENING BEHAVIOR OF TWO TI BEARING STEELS DURING TORSIONAL SIMULATION OF ROLLING.** An industrial controlled-rolling schedule was simulated in hot torsion for two Ti steels. The yield and the maximum stresses of each pass were determined from the recorded flow data. An approach resulting in a new softening parameter based on mechanical flow data is presented here. The evolution of austenite structure was determined from samples quenched after selected passes. The normalized times to 50% softening were determined from both the mechanical and metallographic data for each pass. The increase in Ti level from 0.03 to 0.12% in these steels led to austenite grain refinement in the simulated 'as rolled' material. This improvement was ascribed mainly to TiC precipitation during rolling. (Author abstract) 20 refs.

**091619 FERRITE FORMATION FROM DEFORMED AUSTENITE IN A Ti MODIFIED HSLA STEEL.** The effect of austenite deformation in the recrystallization, partial recrystallization and non-recrystallization temperature range on the subsequent ferrite transformation was investigated in a commercial HSLA steel with 0.076% Ti and a reference C-Mn steel of same base chemistry. The steel samples were given reductions in the range 20-60% at 850, 950 and 1050°C by single pass rolling followed by isothermal transformation to ferrite at 690°C for up to 1800 s. It was found that the austenite to ferrite transformation rate was increased both with increase in the amount of austenite deformation and lowering the finish rolling temperature. The addition of titanium resulted in decrease in the rate of ferrite formation as well as led to the formation of polygonal ferrite grains. Non-recrystallized elongated austenite grains appear to give fine ferrite structure while mixed ferrite grains resulted from partially recrystallized austenite. It was observed that not only the austenite grain boundaries, but also the twin boundaries and/or the deformation bands within elongated austenite grains were found to act as potent nucleation sites for ferrite. (Author abstract) 14 refs.

**091620 SIMULACE PODMINEK DOVALCOVANI MIKROLEGOVANYCH OCELI.** [Simulation of Conditions for Finish Rolling of Microalloy Steels]. A new steel rolling method is proposed which takes into account the fact that during the rolling process at a constant rate with a drop of the Zener-Hollomon parameter Z takes place; this is replaced by a newly defined Z' parameter which is the function of the torsion temperature and rate. The description of the stress/strain curves utilizes this parameter. This makes the complicated computation of the activation energy which is required for evaluating the Z value unnecessary. The method was experimentally verified under conditions of finish rolling of a C-Mn-Nb-V-based microalloy steel. In Czech. 11 refs.

Schindler, Ivo; Zidek, Milan; Boruta, Josef. *Hutn Listy* v 42 n 3 Mar 1987 p 177-181.

**091621 EXPERIMENTAL AND ANALYTICAL INVESTIGATION OF ROLLING CHANNEL SECTION BEAMS.** Where the width/height ratio of the steel slab is large, there is little lateral spread of the material during rolling. However, as the width/height ratio decreases to below unity, the lateral spread increases and its accurate prediction becomes important. In the present investigation rolling tests were performed on rolling rectangular section beams of three different initial shape factors in a three-pass rolling sequence to produce channel section beams. In the absence of theoretical analysis for rolling of shaped sections, approximate methods for determining roll load, roll torque, and lateral spread have been suggested by several authors. These are compared with the experimental results. Approximate theoretical expressions are suggested to calculate roll load, roll torque, and lateral spread during rolling. (Edited author abstract) 15 refs.

**091624 HOCHREDUKTIONSMASCHINE ALS VORUMFORMSTUFE IN EINER KONTINUIERLICHEN DRAHTSTRASSE.** [High Reduction Mill as a Preforming Stage in a Continuous Rod Mill]. With the further development of round casters, the high reduction mill which allows to obtain rolling passes with cross-section reductions of more than 84% in one operation, is gaining importance as a preliminary stage in wire rod mills. It can be used separately, in combination with a shaping stand and as a roughing stand in continuous wire rod or light section rolling mills and allows the rolling both of smooth wire rods and rebars. Experience gathered with an Italian wire rolling mill, on which more than 250,000 tons have been rolled up till now, show that investment and operating cost are more favorable than in the case of conventional plant. (Author abstract) In German.

**091628 ROLLING OF CONTINUOUSLY CAST STRIPS AND THE TECHNICAL CONSEQUENCES WITH RESPECT TO THE DESIGN OF HOT STRIP PRODUCTION PARTS.** After positive experiences with a pilot plant for the casting of transfer bars, rolling tests were carried out on a reversing stand, in a hot strip mill, and in a cold mill in order to confirm the properties of the hot and cold rolled strip. This was followed by the development of process concepts for the manufacture of hot strip which, by comparison with conventional hot strip production plants, offer economic advantages for plants with lower outputs. The rolling tests showed that all steels that are castable on conventional continuous casters can also be produced on the strip caster while exhibiting good surface and mechanical properties. The article then presents the so-called CSP concept (Compact Strip Production), in which the caster is combined with a soaking furnace and a 4-stand finishing mill in one single line. (Edited author abstract) 3 refs.

**091629 INCREASING THE LIFE OF SLIDING PASSES.** The most efficient method of increasing the life of cast iron passes in the leader stand is electrospray alloying with titanium-cobalt alloys of the T5K12 type. The use of cemented steel passes reduce pass breakage to a minimum. The use of bronze passes with a hardness greater than HB 400 is promising for the finishing stand. The heat treatment (quenching and tempering) of gray iron passes increases their durability and reduces the tendency toward metal build-up. The resistance of passes to metal build-up is also increased by optimizing the profile of the working surface of the pass and the chemical composition of the rolled metal. The Magnitogorsk Mining-Metallurgical Institute developed a technology for machining passes of steel 20KhGSMa which makes it possible to obtain an optimum profile and roughness.

Inst, USSR); Isaev, N.M.; Kuznetsov, R.V.; Shulepnikova, A.G.; Svirchevskii, V.I.; Pudov, E.A.; Il'in, M.G. *Metallurgist (USSR)* v 31 n 7-8 Jul-Aug 1987 p 258-259.

**091630 TECHNOLOGY FOR END ROLLING (ORBITAL FORGING) OF THIN FLAT PARTS.** The present work analyzes the metal flow during end rolling (orbital forging). Several new technological processes are proposed, and a method of designing end-rolling technologies is developed. After analysis, the following is the conclusion. 1) Fracturing of the central zone of workpieces is caused by the additional tensile stresses developed in the workpiece center when rolling with tool inclination angles of 3° or more. 2) New technological processes of end rolling (orbital forging) have been developed which provide additional workpiece deformation for sizing disks, piercing holes, or separating rolled rings from a rod. 3) A method is proposed for designing technological processes for end rolling (orbital forging) or flat parts such as disks as rings, achieving large degrees of deformation without fracturing. 8 refs.

Kazachenok, V.I.; Nagovitsyn, V.V.; Zimin, Yu.A. *Sov Forg Sheet Met Stamping Technol n 2* 1987 p 5-10.

**091631 SIMULATION OF RING ROLLING WITH NEW WAX-BASED MODEL MATERIALS ON A FLEXIBLE EXPERIMENTAL MACHINE.** Nowadays, the practice of using model materials for the analogical simulation of most forming processes is well established; however, the practice is almost non-existent in ring rolling. Important new opportunities for ring rolling have arisen due to a remarkable development over the last five years: highly unsymmetrical thin-walled rings and weld-neck flanges are being required to an increasing extent in high-cost materials such as aluminum alloy, stainless and maraging steels, heat-resisting alloys, titanium, magnesium, nickel alloys and suchlike. The present investigation explores the applications of the analogical-simulation method in ring-rolling sequences. For these applications, a new flexible horizontal machine has been developed for the rolling of model-material rings, the outer diameters of which do not exceed 700 mm. Typical rolling examples are concerned with the prediction of rolling forces and torques, with the analysis of flow patterns, and with some operating rules for idler and edging rolls. (Edited author abstract) 26 refs.

**091632 EFFECT OF ROLLING FACTORS ON TOLERANCE OF FINISHED HOLLOW DRILL.** The production of a steel hexagonal hollow drill using a core bar in its center is a process of bimetal combination rolling in which the principle of deformation is specific and complicated. The section accuracy of finished products is thus under the influence of various factors such as pass design, deformation rate, ingot shape type to mill. Tests on the effect of these factors are described. (Edited author abstract) In Chinese. 4 refs.

**091633 TWO STRAND SHAPING TECHNOLOGY.** The authors describe the solutions found by the Pervouralsk Unintegrated Metal Structures Works to the problems entailed in the development of two- and multiple strand shaping. He discusses the possibility of organizing two or more synchronized passes on the work portion of the roll shafts; the possibility of longitudinally parting a double width starting stock to two or more strips directly on the mill; the development of roll and roll pass designs promoting the production of a quality shape in each strand without additional edging rollers, straightening guides, or other devices and the possibility of cutting two or more shapes at a time to measured lengths in final form on the mill. Assimilation of the final two-strand shaping technology and equipment developed raised the productivity of mills for symmetrically bent shapes by an average factor of 1.7. (Author abstract)

**091639 LOADS IN THE PROCESS OF ELONGATING ROLLING IN THE ASSEL MILL.** The results of investigations of the loads accompanying the process of tube rolling in a three-wall oblique Assel rolling mill are

reported. Based on experimental data, relationships between the loads and the following parameters have been defined: tube-diameter decrease;  $\alpha$  - angle of skew of the roll axes from the axis of rolling;  $\beta$  - angle of inclination of the roll axes from the rolling axis when  $\alpha=0$ ; wall thickness and their decrease in relation to the tube diameter. The relationships have been interpreted and the dependence determined between some of them and (i) the coefficient of the axial velocity and (ii) the amount by which the contact length between the tube and the roll is increased due to local deformation of the tube at entry to the roll gap. (Author abstract).

## Analysis

**091640 FINITE ELEMENT STUDY OF FLAT ROLLING.** Using an Eulerian formulation, a finite element solution for the flat rolling problem is presented. Calculations are performed to establish the effects of roll deformation and of the variation of the coefficient of friction in the roll gap on the predictive capabilities of the model. Comparison to data of Al-Salehi et al (1973) and Shida and Awazuhara (1973) indicates that the differences between measurements and calculations decrease when the above-mentioned effects are accounted for. (Author abstract) 28 refs.

**091645 IMPROVING MILL YIELD BY IN-LINE BILLET WEIGHING.** In many plants mill yield (cast billet to prime bar) is increased by adjusting billet length according to product. There is, however, significant variation in the billet weight per unit length because of differences in cross-sectional area and in the density of the as-cast steel. Yield is maximized when billet weight rather than length is controlled. This paper describes weighing equipment which has been installed immediately following caster cut-off units (torches or shears). Billet weight is controlled by adjusting cut-off length to suit prevailing conditions. The adjustment can be manual or by a 'close loop' control system. The yield improvements which are obtained provide very attractive returns on investment. (Author abstract)

**091653 ANALYSIS OF ROLLING OF BARS BY THE ENERGY METHOD USING FINITE ELEMENT DIVISION (ANALYSIS OF SQUARE-OVAL PASS).** In the field of bar rolling, very little theoretical research has been performed because the flow of the material in bar rolling is complicated. Recently, authors proposed a new energy method using finite element division; this method was applied to the analysis of the flow of the material for two types of bar rolling: square-diamond pass and round-oval pass. However, another important type of bar rolling exists: square-oval

pass. The flow of the material of this type differs greatly from that of the former types. In square-oval pass, the material is deformed inhomogeneously, and the degree of freedom of the velocity fields must be increased for precise simulation of the flow of the material. In this paper, authors have improved the method to lessen computation time and memory requirements. This method is then applied to the analysis of the flow of the material in square-oval pass and reasonable results are obtained for rolling properties such as width spread, strain rate distribution, folding of stress-free side surface, and others. (Edited author abstract) 7 refs.

**091658 OPTIMISATION OF BASIC PARAMETERS OF ROLLING COMPLEX FOR PRODUCTION OF BILLETS.** The authors suggest a new integral function for optimisation of a rolling complex for the purpose of increasing its productivity. Modern methods of optimisation are used to determine the best processing conditions and parameters for the roughing mill, hot cutting shears, and continuous mill of such a complex with consideration of the interplay of these conditions and parameters. Use of the method to solve the problem of optimisation of a rolling complex for the production of billets enabled the number of passes required to be reduced from 11 to 9 and the best loading for the edging stands of the continuous billet mill and additional loading for the first two horizontal stands to be obtained with a resultant increase in productivity. (Edited author abstract) 10 refs.

**091661 NEW TWELVE-HIGH REVERSING COLD ROLLING MILL.** A twelve-high cold rolling mill with the blast technology has been put into operation at Metallwerke Schwarzwald, Villingen/Schwenningen, Federal Republic of Germany. A special feature of this rolling mill is the direct hydraulic screwdown system which has been developed by Josef Froehling GmbH. Extremely short reaction times, smallest adjustments and, as a result, closest thickness tolerances are obtained by

means of a separate high pressure hydraulic control loop, operating with servo valves. (Author abstract)

Froehling, Peter (Josef Froehling GmbH, Olpe, West Ger). *MPT Metall Plant Technol* v 10 n 4 1987 p 88, 90.

**091662 EQUIPMENT AND TECHNOLOGY CHARACTERISTICS OF THE NEW TYPE 6-HIGH COLD ROLLING MILL.** This paper presents the equipment, technological characteristics and operational data of the 6-high cold rolling mill with intermediate rolls shifting in axial directions. The roll dimensions are: 110/130/300 dia. 400L mm and 125/150/380 dia. 400L mm. Experimental results regarding the mill modulus curve, the relation between the shifting force of intermediate rolls and the rolling load and speed, the influence of intermediate rolls shifting on the shape change, the shape control function of the work roll bending force, the improvement of the edge drop and the existence of infinite width rigidity are given in this paper. The advantages of the 6-high mill, such as a reduction of edge drops and cracks, the tendency toward heavy reduction, a reduction of the number of passes and intermediate anneals and stability in shaping and performance are confirmed by experiments. With the application of the 6-high mills, the quality and yield of rolled strips, the productivity and the operating efficiency of the rolling mill can be improved. (Edited author abstract) 3 refs. In Chinese.

**091666 COLD ROLLING: THE ALTERNATIVE FOR SPLINED SHAFTS.** Many design engineers, when faced with the task of specifying splines, threadforms and similar features on shafts, still think in terms of conventional metal-cutting techniques. However, there is an important alternative in the cold rolling process which normally offers significant advantages in reducing production cost while, at the same time, enhancing the inherent mechanical properties of the component. There have been more demands placed upon both quantity and quality of the parts produced by cold rolling. As a result, it has been greatly improved over recent years, through better machine and tool design coupled with a clearer understanding of the material requirements of the components being cold formed. The very fact that the metal is made to cold flow in the production of the profile means that the structure of the material is improved in the critical areas and smaller diameter stock can be used.

Lee, Geoff (Marbaix Lapointe). *Eng Mater Des* v 32 n 3 Mar 1988 p 22, 24.

**091667 DEVICE TO MEASURE STRIP TENSION ON COLD-ROLLING MILLS.** One of the important parameters in rolling is the tension of the strip being rolled. The Special Design Office of the Chermatavtomatika Scientific Industrial Association has developed several different tension meters and introduced them on a number of mills for flat rolled products. The tension of the strip is determined by measurement of the vertical component of the tensile force on a sensor built into the bearing of the measurement roller.

**091670 BERECHNUNG DES SCHWINGUNGS-VERHALTENS SCHNELLAUFENDER KALTWALZ-TANDEMSTRASSEN.** [Calculation of the Vibrational Behaviour of High-Speed Cold Rolling Tandem Mills]. In order to investigate the influences of plant data and parameters of the rolling schedule on the tendency of a cold rolling tandem mill to vibration, a mathematical model describing the coupling between the vibrational characteristics of the rolling plant and the elastomechanical processes in the roll gap was developed. With a computer program, based on this model, a better understanding of the mechanisms of the vibration was achieved. A simplified method for comparing different rolling schedules in respect to their tendency to chatter was worked out. (Author abstract) 13 refs. In German.

**091671 ELIMINATION OF DISTORTION NEAR THE CUT-OFF EDGES OF COLD ROLL-FORMED LARGE THICK CHANNELS.** Methods for eliminating the distortion of the cut-off flange edges of a steel channel-section of 4.5 mm wall thickness and 75 mm flange height are experimentally researched, using a punch-die apparatus or press-rolls. The principle of the methods is to compress the flange edge and cause new plastic deformation there, so that the residual stress which occurred during the cold roll-forming process re-distributes, with reduction of elastic recovery during the subsequent dimensional length-cutting operation. Prototype production tests have been carried out and high accuracy products have been obtained. (Author abstract) 5 refs.

**091673 COMPARATIVE ANALYSIS OF ROLLING PROCESS AND PROCESS OF DRAWING ROLLER DRAW PLATES.** The results of the authors' comparative analysis indicate differences between the rolling process and the process of drawing through undriven rollers. The characteristic differences between the process of rolling with tension and that of drawing through undriven rolls arise from the different methods of power transmission for rotating the deforming tools. The stress state of the billet during drawing through roller draw plates is a function of the design of the support bearings of the work rollers. The use of back tension is expedient in the case of drawing through roller draw plates with backup rollers. (Author abstract) 9 refs.

**091675 LENGTH OF CONTACT ARC DURING COLD ROLLING.** A solution is put forward to the problem of determining the length of the contact arc during cold rolling based upon the Hitchcock-Tselikov equation without iterations. The expressions obtained ensure accurate calculation of the length of the contact arc in the case of elastic compression of the rolls and elastic recovery of the strip dimensions once it has left the deformation zone. The limiting values of the ratio of the contact forces of friction to the deformation resistance of the metal that ensure rolling of strip of minimum thickness are established. (Author abstract). 5 Refs.

## Computer Aided Design

**091677 ROLL PASS DESIGN FOR THE ROLLING OF SPECIAL SECTIONS.** Due to the increasing market for special sections, there is a necessity to increase the skill in section pass design. This can be done by presenting a number of good roll pass designs for different sections to get ideas for roll pass design for similar sections and by developing computer-aided roll design systems (CARD). In this paper, roll pass design for rolling of nine different sections is presented with comments on the rolling conditions. These pass designs are from the roll pass design catalogue presented by the Swedish Ironmasters Association (Jernkontoret). CARD systems are complex, but open new possibilities for automation of roll design procedure and roll turning. (Edited author abstract) 32 refs.

## Computer Simulation

**091679 TEMPERATURE SIMULATION AND ITS APPLICATION TO STEEL QUALITY CONTROL IN BAR ROLLING.** A water-filled cooling tube was developed for controlled rolling and cooling of bar, and, based on experimentally obtained cooling characteristics of the tube, cooling ability in the water cooling process was formulated. By incorporating the present formula into a previously developed temperature model; temperature simulation of bar subject to forced water cooling in the rolling process became possible. Operational conditions for controlled rolling and cooling were determined by the simulation, and uniform finegrained structure and hardness were obtained in practical rolling. (Author abstract) In Japanese. 3 refs.

**091683 CAPTEURS DIMENSIONNELS DANS LE PROJET D'AUTOMATISATION DU TRAIN GREY DE DIFFERDANGE.** [Dimension Sensors in the Automation Project of the Grey Mill at Differdange]. In the automation project of the Grey mill at ARBED-Differdange, the dimension sensors are important for a real-time control of the roll stands. During development of the control for the beam dimensions, a two-level approach has been adopted. Level 1 is control of the essential beam dimensions at the intermediate roll stand during different milling cycles. This control is realized at hot milling temperature for the whole length of the beams. Level 2 is dimension control of the beam section and form as they

come out of the finishing stand upstream of the hot saws. For level 1 a combination of CCD cameras, radiometric and laser technics allows continuous measuring of the thickness, height and length of the flanges at a speed of 8 m/s. During level 2 the final control of the form and dimensions of the beams is realized by robotic technics. (Edited author abstract) In French.

**091693 ROLE OF CONSTITUTIVE FORMULATION IN THE ANALYSIS OF HOT ROLLING.** The effect of constitutive modelling of material behavior on the predictive abilities of two models of flat rolling is studied. Comparison of calculated roll forces and powers to those measured on a commercial steel mill indicates that the Orowan model is sufficiently accurate when supplied with carefully determined flow strength data. The manner of representation of that data is found to be significant. The results show that a multidimensional databank, which stores values of strength for specific strains, rates of strain and temperatures is very useful in modelling the process. (Author abstract) 32 refs.

Lenard, J.G. (Univ of New Brunswick, Fredericton, NB, Can); Wang, F.; Nadkarni, G. *J Eng Mater Technol Trans ASME* v 109 n 4 Oct 1987 p 343-349.

**091694 COOLING CONDITIONS OF HOT ROLLED STEEL COILS.** It is established that the effect of the onset of a steady-state temperature field is of a universal nature and can be used for analysis of the cooling processes in hot rolled coils after rolling. The increase in the cooling rate of a coil owing to blowing with a steam of air is attributable to redistribution of the heat flows in the metal and increase in the proportion of heat transfer by convection as cooling progresses. Control of the steady-state cooling condition in the high temperature range (800-700°C) provides the possibility of additional heat treatment of strip wound into a coil, utilisation of the heat in the strip, and a reduction of cooling time in the low temperature range (350°C). (Edited author abstract) 4 refs.

Gasho, E.G. (Moscow Engineering Inst, USSR); Prokhorov, V.I.; Moroz, A.T.; Frantsenyuk, L.I. *Steel USSR* v 17 n 2 Feb 1987 p 86-87.

**091695 PRODUCTION OF ROLLED PRODUCTS OF LOW-CARBON STEELS FOR FINISH STAMPING.** Based on the equipment at the Magnitogorsk Metallurgical Combine for rolling, heat treatment, and finishing and the requirements for the production of hot-rolled products to be subjected to finish stamping, the authors chose a scheme which includes rolling on a continuous hot strip mill, accelerated cooling, cutting of the strip, heat treatment, strengthening, pickling and oiling. The main problem in realizing this scheme was developing a heat treatment regime which would ensure a fully spheroidized structure and low tensile strength. In connection with the absence of an annealability interval for granular pearlite in the case of hypoeutectoid steels, only a subcritical anneal can be employed in bell-type furnaces for sheets of steels 08kp and 20.

**091696 RECHNERISCHE ANALYSE VON WALZEIGENSPANNUNGEN.** [Numerical Analysis of Residual Rolling Stresses]. A numerical method is presented with the aid of which the formation of residual stresses in hot-rolled sections during cooling after the rolling process can be simulated on a computer. The bases of the theoretical assumptions are explained. The temperature dependent thermal and mechanical properties of structural steel are given as a basis for the calculation

procedure. The processes in a hot-rolled I-beam during cooling are illustrated and explained by a numerical analysis. For the first time, the distribution of residual stresses in a bar with a square cross section, which has been known by measurement on the surface only, could be determined by calculation. (Edited author abstract) In German. 21 refs.

Hamme, U. (Bergische Univ Wuppertal, Wuppertal, West Ger); Schaumann, P. *Stahlbau* v 56 n 11 Nov 1987 p 328-334.

**091697 INVESTIGATION OF TEMPERATURE FIELDS IN BEARING STEEL BAR COILS DURING COOLING AFTER HOT ROLLING.** Unevenness in the temperature distribution within coils during cooling after hot rolling has a marked influence on the microstructure and mechanical properties of the metal. Study of the temperature conditions during cooling of coils is therefore important for determining accurate process parameters in the hot rolling of steel. In this project the authors experimentally and theoretically determined the temperature distribution over the cross-section of bearing steel rod coils during cooling after hot rolling to different schedules. The thermal conductivity equation for a cooling coil in a cylindrical coordinate system can be written in the following form. The authors theoretically and experimentally determined the temperature fields and changes in this field over the cross-section of bearing steel ShKh15 rods during cooling as a function of coil weight and dimensions, cooling start temperature, and cooling conditions. (Edited author abstract) 3 refs.

**091698 TEMPERATURE DISTRIBUTION IN A SLAB DURING HOT ROLLING.** The dependence of the temperature distribution during hot rolling of a steel slab on the speed of rolling, reduction and initial temperature is investigated. It is observed that while the center of the slab cools, the surface loses heat at a much higher rate following which significant reheating occurs. Because of that different parts of the slab receive significantly different thermal-mechanical treatments, possibly resulting in a nonhomogeneous product. (Author abstract) 49 refs.

Karagiozis, A.N. (Univ of Waterloo, Waterloo, Ont, Can); Lenard, J.G. *J Eng Mater Technol Trans ASME* v 110 n 1 Jan 1988 p 17-21.

**091699 FRICTION AND FORWARD SLIP IN HOT ROLLING.** Relations between forward slip and the coefficient of friction in flat rolling were determined by a computer program Friction-Hill. This program gives a numerical solution to von Karman's equation. The relation between forward slip and the coefficient of friction is dependent on the model of friction, geometry of rolling, deformation of the rolls, elastic entrance and exit regions, and model of yield stress of the material in the bar. The conclusion is that to evaluate coefficients of friction from measurements of forward slip in hot rolling by application of a simple equation is unreliable. (Author abstract) 14 refs.

**091703 DEVELOPMENT OF TECHNOLOGY AND EQUIPMENT FOR THERMOPLASTIC HARDENING OF ROLLED METAL - PROSPECTS FOR IMPROVING THE QUALITY AND SAVING METAL.** A new method is proposed for rolled metal hardening by means of high-speed sign-variable plastic bending, i.e. thermoplastic treatment. This process makes it possible to do without bulky and complex equipment. The effect of the sign-variable bending on the metal structure results in an increase of its uniformity over the entire cross section, refinement of all the elements of the structure. It brings about orientation of martensite crystals with respect to the deformation axis. Thermoplastic treatment stably improves the strength characteristics of carbon and low-alloyed steels by 15-20% and impact toughness by a factor of 1.5-2 in comparison with conventional hardening. (Translated author abstract) In Russian.

**091704 FERRITE GRAIN REFINEMENT THROUGH ACCELERATED COOLING AFTER CONTROLLED ROLLING IN LOW CARBON STEELS.** The authors studied the transformation behavior and ferrite nucleation in continuous and isothermal transformation. A combination of strain imposed in the uncrystallized region and an increase in supercooling by accelerated cooling caused an increase in intragranular nucleation which resulted in ferrite grain refinement. The number of intragranular nuclei decreased as recovery and recrystallization progressed before transformation. It is suggested that intragranular nucleation sites were dislocations, the sub-grain boundary and inclusions which could not act as nucleation sites under conditions of controlled rolling. Accelerated cooling brought about ferrite grain refinement by promotion of intragranular nucleation on the proper sites and suppression of grain growth. (Edited author abstract) 17 refs. In Japanese.

**091708 ON THE STRAIN RESISTANCE OF STEEL DURING HOT ROLLING.** The static softening of steel during the pauses between deformation stages can be described by an expression covering the effects of temperature, strain rate, and degree of previous deformation. The proposed procedure is capable of determining the strain resistance of steels during hot rolling, allowing for failure to soften completely between passes. The calculated results agree closely with experimental data. 9 refs.

**091711 ACCELERATED COOLING: A PHYSICAL METALLURGY PERSPECTIVE.** In the 25 years that accelerated cooling has been used in the production of steel, its role has undergone drastic changes. In 1962-1970, it was used exclusively on hot strip mills, mainly to reduce the length of run-out tables otherwise required for low temperature coiling. The unexpected benefits spawned research and development which has continued to the present. There have been significant advances made as a result of this interest. Among the first was the appreciation of the importance of the condition of austenite prior to cooling. Later work on alloy design and process variations led to improvements in ferrite-pearlite steels and the development of multiphase steels for strip and plate applications. The dual-phase (as-rolled) strip steels and ferrite-bainite plate steels are examples of important developments. These steels offer final properties which were not available in earlier times. The purpose of this paper is to discuss accelerated cooling from the viewpoint of how cooling rates and continuous cooling transformation (CCT) diagrams can determine the sequence of phases which form and how physical metallurgy principles govern their amounts and distributions. Of principal interest are (i) the factors which control the hot rolled microstructure of austenite, (ii) the influence of austenite microstructure and composition on the CCT diagram, and (iii) the influence of cooling path on microstructure evolution for a given CCT diagram. (Edited author abstract). 80 Refs.

**091712 ASSIMILATION OF TECHNOLOGY FOR PRODUCTION OF FEEDSTOCK FOR HIGH PRECISION SHAPED SECTIONS ON 300 MILL WITH FOUR ROLL PASS.** An examination is made of technology for the production of high precision shaped sections developed on the basis of experimental investigations of temperature and deformation schedules for rolling rounds in a four roll pass. The use of a rolling stand with a universal four roll pass enables rectangular and square sections to be produced with identical edge radii. Implementation of the technology has made it possible to dispense with a number of drawing conversions, reduce the number of anneals and surface preparation operations, lower metal consumption, and simplify the manufacture of high precision steel shaped sections. (Author abstract). 4 Refs.

**091714 PROFILE AND SHAPE CONTROL IN HOT STRIP MILL.** A profile and shape control system has been developed for use in hot strip mills at Wakayama Steel Works and Kashima Steel Works. The control system consists of variable crown (VC) rolls, work roll benders and work roll shifting devices on the last three stands of the finishing train. These devices can be preset so that the desired strip profile can be obtained. To achieve this, mathematical models were developed which could be used to calculate the thermal roll crown, roll wear, VC roll profile and strip profile. These models are suitable for online calculations. (Edited author abstract). 11 Refs. In Japanese.

**091716 IMPROVEMENT OF ECONOMICS AND PRODUCT QUALITY IN STRIP MILLS THROUGH HIGH-TECH ROLLING-PART 1: HOT STRIP MILLS.** During 1987 SMS Schloemann-Siemag introduced a new technology for the economical manufacture of hot strip. The technology is known as compact strip production. It is based on a continuous caster which produces 40 to 50 mm thick strip at a production capacity equivalent to that of a modern slab caster. The quality of these strips enables their direct entry into a hot strip finishing train. The new technology marks the end of the use of the complete roughing train in hot strip production plants. It will also remove a technical problem which is a determining factor for the current hot strip roughing train, namely, matching the transfer bar width to that of the strip. 5 Refs.

**091717 EFFECTS OF HOT ROLLING TEMPERATURE AND SOLUTE CARBON ON DRAWABILITY OF HOT ROLLED IN FERRITE REGION AND ANNEALED SHEET STEEL.** The effects of the solute carbon content during hot rolling and the hot rolling temperature in ferrite region on the recrystallization texture and Lankford value of extra low carbon sheet steels were studied. The conclusions are: 1) With the addition of Ti or Nb effective in raising the recrystallization temperature of the extra low carbon steel, the hot rolled texture becomes nearly the same as the cold rolled one even though the rolling temperature is 700-800°C. The effects of hot rolling temperature in ferrite region on the hot rolled and hot rolled-annealed textures of interstitial free sheet are small. 2) Solute carbon content during hot rolling is one of the most important factors that affect the recrystallization texture. When decreased the solute carbon content during hot rolling by carbide (TiC, NbC) precipitation, recrystallization texture of {554} <225>

orientation is developed after annealing. That is nearly the same as the cold rolled and annealed texture. (Edited author abstract). 15 Refs. In Japanese.

**091718 SCALE-BREAKING OF HOT-ROLLED STRIP WITH RUBBER ROLL.** Hot rolled strip at high coiling temperatures for continuous annealing can be effectively pickled if the scale formed on the surface is cracked beforehand. Such cracking is commonly achieved by tension leveling or skinpass rolling. A rubber roll rolling method in which bending strain is applied to steel strip by passing it between a rubber roll and steel roll has proved effective in enhancing pickling efficiency. 2 refs.

**091719 EFFECTS OF FINISH-ROLLING TEMPERATURE AND CARBON CONTENT ON MICROSTRUCTURE AND MECHANICAL ANISOTROPY OF 0.04 - 0.13% C STEELS.** Steels with carbon content from 0.13 to 0.04% were rolled in the temperature range 1 220 to 750°C and air cooled. The grain size gradually decreased with lowering rolling temperature and then increased with further lowering of rolling temperature down to the ferrite range. Rolling in the ferrite range produces a strong anisotropy in tensile ductility. (Edited author abstract) 7 refs.

**091721 DEVELOPMENT OF A SIMULATION TESTING MACHINE FOR EVALUATING THE LUBRICITY OF LUBRICANT IN COLD SHEET ROLLING.** In a new type of simulating test, it is necessary to deform the workpiece material plastically which is different from the Timken test. The contact behavior between rolls and workpiece is closer to that in rolling practice. The roll can be rotated at a high relative speed and the normal force and tangential force can be measured individually. The simulation testing machine developed is sufficient for these conditions. **091727 THIN-WALLED PIPE ROLLING ON A SMOOTH FORMER IN ELLIPTIC PASSES.** The present paper applies the flow theory of A.A. Ilyushin to the process of lengthwise rolling of thin-walled pipes. The distinctive features of this process are the presence of priorly unknown loads at the boundaries of the flow region and the variability of the circular liner velocity of the points of the roll surface with respect to the pass width. Equations can be derived to describe lengthwise rolling of pipes under the assumption of a smooth former. Based on a solution of the equations that have been derived, the conditions are formulated providing the absence of adhesion areas in the deformation focus; analytical expressions are given for estimating the stresses on the front and back of the deformation focus inaccessible to direct measurement through measurable quantities, such as the speed of the rolled pipe at the entry and exit of the pass. For the area adjacent to the pass apex, the results can be used to establish a correlation with the data on the rolling of thin sheets, corrected for tension. (Edited author abstract) 6 refs.

**091728 PROCESS CONTROL SYSTEM OF SUMITOMO'S HOT WELDED STEEL PIPE MAKING MILL (SW METHOD).** A new pipe-making process named the 'SW method' developed for the continuous butt-welding pipe mill was put into operation at the Kashima Steel Works in 1985. The special features of the new pipe-making system are its ability to carry out welding at high temperature conditions by using a high frequency induction welder and to remove the weld bead by a cut-off device just after welding. The pipe is then continuously reheated in the furnace to get a circumferentially uniform temperature for the following stretch reducing process. In this paper, the electric and computer control systems of the SW method are introduced. The major computer control systems are as follows: (1) Automatic pipe wall thickness control. (2) Automatic welding heat input control. (3) Automatic furnace combustion control. (Author abstracts) 8 refs.

**091729 PRESSURE OF METAL ON ROLLERS IN LENGTHWISE ROLLING OF PIPE.** On the basis of a generalization of the theory of flows of thin layers of plastic substances over surfaces to the case of arbitrary boundary loads, we investigate the contact pressure distribution in the case of lengthwise rolling of thin-walled pipe on a smooth mandrel. The solution of the equations of the first fundamental problem of flow theory is determined by the successive-approximation method. We introduce the concept of critical number, whose value characterizes the presence or absence of sticking zones at a deformation site. We investigate the effect of the rolling parameters on the position of the point of application of the maximum contact pressure. We give the distributions of the normal contact stresses and formulas for the total pressure of the metal on the roller in one particular case of distribution of the boundary loads. (Edited author abstract) 4 refs.

**091736 DEVELOPMENT OF HIGH SHAPE FACTOR ROLLING TECHNOLOGY AND ITS APPLICATION TO MANUFACTURING THICK STEEL PLATES WITH 50 kgf/mm<sup>2</sup> GRADE HIGH TENSILE STRENGTH FOR ARCTIC SERVICE.** Improvement of toughness in thick rolled steel plate and a manufacturing procedure for getting uniform properties over the whole thickness were studied. High shape factor rolling (large roll diameter and large reduction per pass) brought about excellent toughness at the mid-thickness. Simulation experiment and rigid plastic finite element method (FEM) analysis showed that high shape factor rolling increased the rolling effect and resulted in fine ferrite grain size. The thick steel plate with 50 kgf/mm<sup>2</sup> tensile strength can be used for arctic service. (Edited author abstract) In Japanese. 23 refs.

**091739 TECHNICAL FEATURES OF PLATE-ROLLING ON THE 3000 MILL.** The 3000 mill at the Il'ich Zhdanov Metallurgical Combine is used to make plates 8-25-mm thick, 1500-2700-mm wide, and 12.1-24.2-m long. The plates are made of low-alloy structural steels of the 09G2FB type and are rolled in a controlled regime. The mill is also used to make plates of ordinary and low-alloy steels which are rolled in the standard regime. The article identifies shortcomings of the mill and gives recommendations for improvements.

Kononov, Yu.V. (Il'ich Zhdanov Metallurgical Combine, USSR); Popov, N.N.; Nalcha, G.I.; Vinnik, M.V.; Zarya, A.V. *Metallurgist (USSR)* v 31 n 3-4 Mar-Apr

1987 p 57-58.

**091740 STARTUP OF THE PRODUCTION OF TWO-LAYER PLATES AT THE COMBINE.** The Kommunarsk Metallurgical Combine began to master the production of bimetallic plates in 1959. Packets of bimetallic plates weighing 0.5-1.4 tons and measuring 8-24 × 1400-1600 × 4000-7500 mm are rolled on the two-stand 2800 plate mill at the combine. The grades of steel used for the base layer are steels VSt3sp, 20K, 16GS, and 09G2S. The steels used for the cladding layer are steels 12Kh18N10T, 08Kh18N10T, 08Kh13, 10Kh17N13M2T, 10Kh17N13M3T, 06KhN28MDT, 08Kh17N15M3T, and other steels. To improve the mechanical properties of plates with base layers of steels 16GS and 09G2S, quenching and tempering is used in place of normalizing.

Khoroshilov, N.M. (Kommunarsk Mining-Metallurgical Inst, USSR); Barbashev, B.M.; Musikevich, V.F.; Ostapenko, V.M.; Lutsenko, V.A.; Yakimenko, S.G. *Metallurgist (USSR)* v 31 n 3-4 Mar-Apr 1987 p 92-93.

**091741 SPECIAL FEATURES AND OPERATIONS OF THE FUKUYAMA PLATE MILL.** The new Work Roll Shift (WRS) Mill was installed at the Fukuyama Steel Plate Mill in November 1985 in order to improve quality, yield, and productivity. It was the first time that the WRS mill was used in plate rolling. The remarkable feature of this mill is its ability to control the plate crown and shape with work roll shifting (1000 mm stroke) and powerful work roll bending. Then we achieved perfect Schedule-Free Rolling and succeeded in reducing the plate crown. After careful investigation for the design, we achieved low stress and a sufficient level of safety in spite of a large pressure load and a high torque rate. This paper describes the technology for the design, specification, control system, and operation of the mill. (Author abstract) 2 refs.

**091743 OPTIMIERUNGSSTRATEGIE UND MODELLEBILDUNG FÜR DAS GROBBLECHWALZEN.** [Optimization Strategy and Model Structure for Heavy Plate Rolling]. The optimization of a heavy plate mill is designed to ensure extremely exacting thickness, width, flatness and shape tolerances, and accurate tensile strength, yield point and notched bar test toughness values. Further aims are the minimization of energy consumption, the maximization of steel yield, and the reduction of the load on the plant. The report describes the structure of a process control model, which allows to control the forming process and temperature variation in regard of the above mentioned variables. In German. 4 refs.

**091744 SAVING METAL BY EFFICIENT MANUFACTURE ON PLATE MILLS.** An examination is made of a procedure for calculating optimum parameters for the manufacture of carbon and low alloy steel plate on a 3000 mill. The efficient size and weight of slabs for production of plates and skelp are determined. The proposed means of efficient manufacture enables finished stock to be obtained without additional cropping in the range of plates rolled in the minus tolerance field and thereby makes it possible to achieve a saving in metal and production costs. (Author abstract) 3 refs.

**091746 DEVELOPMENT OF A PROCESS FOR MANUFACTURING TRIMMING FREE PLATES.** This paper reports a method for manufacturing trimming-free plates on the basis of analysis of edging characteristics in lead model tests, the features of a commercial edger and its control system and squaring characteristics of the edge in production rolling. Width reducing efficiency is small in V rolling. A small amount of width screw-down improves the efficiency. Width loss can be reduced by a combination of chamfer rolling with finish edging. Automatic width control is necessary for accuracy. (Edited author abstract) 11 Refs.

**091747 TRENDS IN PLATE QUALITY IMPROVEMENT.** A rolling method has been developed based on a nonuniform deformation over the width due to the use of rolls with annular grooves in the roughing stands. This method improves mechanical properties of final products, stabilizes the width, raises yield, leads to better scale removal conditions, and increases mill capacity. Testing of the plate and strip rolling method demonstrated that the rectangular shape of the products was improved and 1-1.5% of material was saved because of a lower scrap rate. The effect of rolling method on impact energy was evaluated using a 09G2 steel slab. (Edited author abstract) 6 Refs.

**091748 METAL FLOW IN THE DEFORMATION ZONE DURING ROLLING IN ANNULAR-GROOVED ROLLS.** The plate rolling process in annular grooved rolls has the following stages (1) working of a smooth surface slab in grooved rolls and (2) working of a variable thickness slab in the transverse direction using grooved rolls. The first process stage was investigated by physical simulation using a laboratory mill. Lead specimens were used. A set of differential equations is solved to derive analytical relations for calculating velocity field components which describe the kinematic state of a slab in the deformation zone during rolling in annular grooved rolls. (Edited author abstract) 6 Refs.

**091751 ENERGY AND FORCE PARAMETERS DURING ROLLING WITH BENDING.** A kinematically permissible velocity field for rolling with bending has been plotted in order to calculate the upper rolling power limit. The field includes two rigid zones separated by the arc of a circle. A field of characteristics for determining the lower power limit has also been plotted. Rolling power and torque have been computed. The results make it possible to predict where rolling with bending requires a lower power than conventional rolling involving straight motion of rectilinear outer zones. (Author abstract) 2 Refs.

**091757 POWDER ROLLED STRIP - A SUCCESS STORY AT MIXALLOY.** Over the past five years Mixalloy Ltd. in Mold, North Wales, has succeeded in commercializing the production of powder rolled strip using the slurry process from a number of alloys including nickel, cobalt and copper based compositions. MPR recently visited the company and Amanda Weaver reports on the latest production developments and new product innovations. (Author abstract)

Weaver, Amanda. *Met Powder Rep* v 42 n 9 Sep 1987 p 598-599, 602-603.

**091758 CHARACTER OF DENSIFICATION ZONE FORMATION IN THE ROLL-CLADDING OF A BASE WITH A POWDER.** Changing the curvature of the working surface of one of the rolls in the rolling of metal powders affects the thickness and density of the resultant strip. In this connection, it is proposed that the following four variants of powder rolling should be distinguished: between rolls of the same diameter, between rolls of different diameters, between a roll and a flat plate, and between a roll and the inside surface of a ring. A common application of the third variant is roll cladding of one or both sides of a base with a powder. In this work, the results obtained are evidence that the third variant of rolling gives scope for increasing the thickness of rolled powder strip and productivity of mills. Use of a base enables the productivity of powder rolling mills to be increased three to four times and strip 1.5-1.8 times thicker to be obtained with rolls of the same diameter as in rolling by the first variant. 4 refs.

**091759 DEFORMATION AND COMPACTING OF POWDER BILLETS IN INITIAL STAGES OF ROLLING OF SECTIONS.** Rolling in grooves of capsules containing sprayed steel powders is characterized by special features. The rate of hardening the powder mass in rolling in the first groove is determined by the strain and angle of inclination of the walls of the groove. The

hypothesis of the equality of the perimeters of the powder billet prior to and after rolling has been confirmed for single-pass rolling cylindrical capsules with the powder in various grooves. The maximum compacting of the powder without overfilling the groove is obtained using an oval groove with an axes ratio higher than 3. 7 refs.

**091763 INCREASE IN WORK CAPACITY OF ROLL MOUNTINGS OF WIDE STRIP MILLS.** The authors conclude from analysis of the design and functional parameters of three types of work roll and back-up roll mountings used on the roughing and finishing trains of 1700 and 2000 continuous wide strip mills for hot rolling, that the version employing coupled but independently mounted upper and lower work roll and back-up roll sets has the greatest advantages. Preliminary skewing of the work rolls relative to the stand center line in the

same direction, is recommended for ensuring that the center lines of the work and back-up rolls coincide during rolling (after the bite). This reduces the dynamic axial and radial loads on the mountings and their bearings, thus increasing the work capacities of the latter. (Edited author abstract) 3 refs.

**091764 TEMPERATURE VARIATION ACROSS WIDTH OF STRIP DURING COLD ROLLING.** The nature of the temperature distribution over the width of strips rolled on twenty-roll and four-high 450 mills (corrosion resistant steel in four stages with intermediate recrystallization annealing) was established experimentally. It is demonstrated that the transverse distribution irregularity of the temperature influences the shape of the final strip, giving rise to increase in waviness and decrease in warping. In developing the modes of deformation and roll profiling ensuring that the strips are flat after rolling, the nature of the change in the temperature irregularity across the width has to be taken into account. (Edited author abstract) 3 refs.

**091767 REDUCTION IN STRIP TEARING DURING STOPPING AND STARTING OF A CONTINUOUS COLD-ROLLING MILL.** This study showed that the sections of reduced thickness are critical sections where the strip tears during startup of the mill and fluctuation of interstand tension. Tearing is particularly frequent between the last two stands, where the thickness of the strip is minimal. To avoid the formation of sections of lower than normal thickness, the authors developed an automatic system to relieve the rolling forces and moments on the mill when it is stopped with strip in the stands. The system provides for a smooth reduction.

**091777 EXPERIENCE WITH THE NIPCO SYSTEM IN STRIP AND FOIL ROLLING.** The basic element of the Nipco system is the hydraulically controlled Nipco roll. In four-high rolling mills, it is used instead of a conventional back-up roll, while in skin-pass mill stands with only two rolls it is used as a work roll. This roll assumes the tasks of the generation of rolling forces, roll push-up, width setting, local flatness corrections, and replacement of roller bearings. The above

characteristics make the Nipco roll an ideal actuator in the rolling mill. The Nipco system integrates the individual modules of roll, roll chocks, hydraulics, controls, and software into one entity. (Author abstract)

**091782 INSPECTION OF GROUND ROLLS - THEORY INTO PRACTICE.** Today's customers for wide steel and aluminium strip are able to shop around for the best quality at the most favourable price - a direct consequence of overcapacity. To retain their market share, producers are being forced to match the quality demands of the market and a major factor in the battle is a reputation for supplying strip with consistently good shape or flatness. This article describes a new roll inspection and designed to ensure that every roll sent forward to the mill has the specified profile. It makes use of the three probe technique. (Edited author abstract) 1 ref.

Armstrong, D.A. (Open Univ in Wales, Cardiff, Wales); Thomas, R.H.; Murray-Shelley, R. *CME Chart Mech Eng* v 34 n 11 Nov 1987 p 44-47.

**091783 INFLUENCE OF STRIP SURFACE MICROROUGHNESS ON ROLLING PARAMETERS.** The authors conducted investigations in laboratory mills with roll diameters of 100, 200m and 250 mm rolling 1.05-1.85 mm thick aluminium strip and 1.05-1.37 mm thick 08ps steel strip. During rolling with low reductions in ground rolls, some increase in the friction coefficient is observed with increasing surface microroughness. With  $R(\text{a surf.}) > 2.5 \mu\text{m}$ , however, the friction coefficient tends to decrease. An increase in the strip microroughness to  $R(\text{a surf.}) = 4.4-5.7 \mu\text{m}$  during rolling in shot blasted rolls results in a drop in the friction coefficient. 2 refs.

**091784 CRITERIA FOR THE PREVENTION OF SPLIT ENDS.** A criterion for the prevention of split ends (alligatoring)  $A$  is expressed mathematically. This criteria,  $t_0/R_0 > 1.81 \times (t_0/t_f - 1)$  is derived through the extension of an earlier upper bound solution for strip rolling of a perfectly plastic mises material. The treatment is based on the division of the deformation region to a series of triangles, undergoing rigid body rotational motions. (Author abstract) 13 refs.

Zhu, Y.D. (Lehigh Univ, Bethlehem, PA, USA); Avitzur, B. *J Eng Ind Trans ASME* v 110 n 2 May 1988 p 162-172.

**091785 PREVENTION OF CENTRAL BURSTS DURING ROLLING.** An upper bound analysis has been developed to model the flat rolling of a perfectly plastic material. This field permits the possible formation of an internal void. The process conditions under which it is energetically favorable for a void to develop have been determined. It has been found that internal void formation (central burst) is more likely to occur in thick strips and sheets when small reductions are taken. Both front and back tension tend to promote the development of a central burst with the back tension reducing the safe, noncentral burst domain to a greater degree. Criteria curves for the central burst domain and the safe domain are presented for a wide range of process variables. (Author abstract) 21 refs.

**091786 CVC TECHNOLOGY FOR COLD ROLLING MILLS - PLANT EXAMPLES.** Continuously variable crown (CVC) is a new yardstick for quality in hot and cold rolling. Strip flatness and profile can be controlled by CVC technology that provides a continuously adjustable roll gap crown. The technology also incorporates horizontal stabilization of slim work rolls, roll bending and a closed-loop control system including thermal flatness control. Some installations in West Germany are described.

**091788 CONTROLLED ROLLING OF A LOW CARBON STEEL IN WIDE STRIP MILLS.** The combined effects of initial finishing temperature and

cooling between the finishing stands of a wide strip mill on the mechanical properties of steel 3sp were investigated. It was shown that cooling between the stands and a higher initial finishing temperature have no detrimental effect on strength, ductility and impact properties of this steel. A combination of cooling in the intermediate roller table to about 900°C and cooling between the stands is necessary for improving the low temperature properties of steel. The recommended final finishing temperature for a low carbon steel with a guaranteed strength level lies at the beginning of the  $\gamma$ - $\alpha$  transformation range, i.e., at 800-780°C. (Author abstract)

**091789 CROWN AND SHAPE CONTROL IN HOT FINISHING MILL.** In order to meet the demands for high accuracy of strip crown and flatness, the Kakogawa hot finishing mill has been remodeled to work roll shift mill. Various new systems for computer control of strip crown and flatness in the work roll shift mill have been developed and the entire control apparatus has been renewed. As a result of these reformations, accuracy of strip crown and flatness has greatly improved. (Author abstract) 4 refs. In Japanese.

**091792 ERFABRUNGEN BIE DER INBETRIEBNAHME EINER NEUEN PRODUKTIONS-LINIE FUER SONDERWERKSTOFFE, CuSn6-BAND UND BUNTMETALLPLATTIERTES STAHLBAND.** [Experience with the Start of a New Production Line for Special Materials, CuSn6 Strip, and Steel Strip Cladded with Non-Ferrous Metal]. The dynamic development of electric engineering and electronics and thus the increased demands on surface quality as well as on the geometrical and mechanical properties of cold-rolled strips resulted in re-equipping and extending an existing production line for strips of special alloys, bronze and non-ferrous clad materials. By utilizing a new process engineering technique, the fundamentals were provided to continuously supply microelectronics with semi-finished and finished high-grade metallurgical products. New engineering steps of production were established to improve the quality. During the start-up period, new techniques were initiated. The cooperation with the Freiberg Mining Academy and VEB Edelmetallwerk Freital resulted in a further improvement by employing high-tech equipment, and the output was also substantially increased. **091796 STABILITY OF STRIP IN ELONGATING PASSES OF LIGHT SECTION MILLS AND ROD MILLS.** The condition of natural stability during the rolling of an oval strip in round and edging oval passes was determined. Natural stability is observed in round passes with relatively large reductions which decrease in edging oval passes with increase in their height/width factor. From the point of view of stability and uniform loading of the adjacent stands, flat oval passes with flats equal to 0.3 to 0.4 of the width of the pass are rational for an oval-round pass system. Displacement and overflow of the grooves have the greatest influence with respect to loss of stability. (Author abstract). 3 Refs.

**091797 SHAPE STABILITY OF COILS OF HOT ROLLED STRIP.** An investigation was made into the sagging of coils of hot rolled strip conveyed in horizontal and vertical attitudes to a stock bay and stacked there in a single tier and multiple tiers on a flat surface. It is demonstrated that transferring these coils on cradles with wall inclinations of 35-40° from the coils of the hot wide strip rolling mill to the stock bay in a horizontal attitude and stacking them 1-3 high in a horizontal attitude on these cradles is the best method of preventing their sagging during cooling with resultant difficulties during

subsequent processing. The coils cool more rapidly and almost uniformly when stacked horizontally. (Author abstract). 8 Refs.

**091799 FUNDAMENTAL STUDY ON SNAKING IN STRIP ROLLING.** Three-dimensional analysis for strip rolling, in which elastic deformation of rolls and plastic deformation of a strip are treated as one system, is expanded to calculate the nonsymmetric deformation of both rolls and strip. The analysis is applied to evaluate the off-centering or cambering of a strip and the fundamental characteristics of snaking of a strip. The phenomena of nonsymmetric rolling and off-centering or cambering can be predicted accurately by the analysis. (Author abstract). 8 Refs.

Ishikawa, Takashi (Nagoya Univ, Nagoya, Jpn); Tozawa, Yasuhisa; Nishizawa, Jun. *Trans Iron Steel Inst Jpn* v 28 n 6 1988 p 485-490.

**091800 OPTIMISATION OF INTERSTAND TENSIONS DURING CONTINUOUS STRIP ROLLING.** Interstand tension regimes have a considerable influence on dimensional and geometrical accuracies of rolled strip. Rolling strips under optimum interstand tension conditions on the 2000 continuous strip mill in the Cherepovets Iron and Steel Combine enabled the thickness variation of the sheet to be lowered by an average of 0.05-0.15 mm, the width variations to be lowered by 7-8 mm, and the flatness to be increased by 5-10 mm m<sup>-1</sup>. A regime of interstand tensions giving considerable improvement in dimensional and geometrical accuracy indices of the final sheet was developed from the results of the investigation. (Edited author abstract). 3 Refs.

**091801 INFLUENCE OF SKIN PASS ROLLING TEMPERATURE ON POWER-FORCE PARAMETERS OF PROCESS AND QUALITY OF ROLLED PRODUCT.** The authors established the influence of the temperature and amount of deformation of strip on the power-force parameters of the process and properties of 08kp, 08Yu, and 2011 steels during skin passing. To obtain minimum yield strength and hardness values in an 08Yu type steel, the amount of deformation during skin passing must be lowered with increase in temperature. Skin passing with a reduction of 5-9% is recommended in the case of 2011 electrical engineering steel. Varying the skin pass temperature in the 40-200°C range has no influence on its magnetic properties. Considering the positive influence of an increase in temperature on the

power-force parameters of the skin passing process, 2011 steel strip is ideally rolled at temperatures between 100 and 200°C. (Author abstract). 11 Refs.

**091804 BENDING OF STRIPS WITH ONE-SIDE THICKNESS VARIATIONS DURING ROLLING.** Theoretical and experimental investigations of strip curvature during rolling of wide strip have been carried out. The strip had a cross section with a vertical symmetry axis and one-sided thickness variation resulting in convexity or concavity over the width. The concept of additional stresses has been used to develop expressions for the curvature of the workpiece at the roll inlet and outlet. It has been found that during rolling of strip with the cross section the workpiece bends toward the wide face at the roll inlet and outlet and that the curvature is determined by the deviations of cross section shape and area from those of a rectangular section strip. (Author abstract).

**091807 EFFECTIVE COOLING OF WORK ROLLS IN STRIP ROLLING.** An examination has been made of the effectiveness of roll cooling as applied to strip rolling, taking into account practical considerations such as the spray location and positioning, coolant flowrate, and rolling temperature. It is indicated by the results that, for cold rolling, the most effective cooling can be achieved by commencing spray cooling at the exit side of the roll gap and by providing a large spray contact angle. However, for hot rolling, cooling should commence at least 45° from the roll gap exit and a high spray flux density with relatively small spray contact angle is more appropriate. (Author abstract). 30 Refs.

**091816 IMPROVING THE RELIABILITY OF UNIVERSAL SPINDLES.** Statistical studies of the performance of the universal spindles on the 1150 slabbing mill and the roughing stands of the 1700 hot strip mill at the Karaganda Metallurgical Combine established that the main reason for spindle failure is wear of the contact surfaces of the bronze bushings and spindle heads. This wear changes the service conditions of elements of the hinge, leads to shock loads, facilitates the deposition of scale and water on the friction surface, and diminishes the reliability of the spindles. Experience shows that the bronze bushings usually begin to wear from the peripheral sections. To alleviate the concentration of contact stresses during the initial stage of the run-in period, it was suggested that the bushings be provided with chamfers. The design change improved the service life of the spindles.

**091817 NEW METHOD FOR UNIVERSAL ROLLING OF LARGE H-BEAMS FROM CONTINUOUSLY CAST SLABS.** In the structural shape mill at Kashima Steel Works of Sumitomo Metal Industries, Ltd., all large H-beams ranging up to H900×300 and H500×500 have been produced by rolling 250-mm thick continuously cast slabs in one heat with a new split rolling method. Compared with the conventional rolling method which starts from ingots, the rolling yield has been raised by 10%. Energy consumption has been significantly improved. (Author abstract). 6 Refs.

Hayashi, Chihiro (Sumitomo Metal Industries Ltd, Amagasaki, Jpn); Kusaba, Yoshiaki; Nakayama, Katsuichi. *Trans Iron Steel Inst Jpn* v 28 n 6 1988 p 428-433.

**091818 PREVENTION OF BUCKLING IN HEAVY WIDTH REDUCTION WITH LONGITUDINALLY INCLINED EDGING ROLLS.** Heavy width reduction has become increasingly important in the production of hot steel strip. When a thick slab is subjected to heavy width reduction, the rolling force is too great, therefore the edge must be larger. On the other hand, when a wide slab is subjected to heavy width reduction, most slabs buckle convexly upwards along the transverse direction. It was an objective of this study to develop an improved method to reduce heavily the width of thin materials without transverse buckling. A new edger rolling method with a pair of edging rolls tilted in the entry direction was developed. When the edging rolls are tilted in the entry direction, the vertical force is applied upward to the edges of the slab. The resultant vertical force and transverse force of edge rolling bends the slab convexly downwards. When heavy reduction is applied to a slab bent in this manner, slab bending is constrained by the table rollers and buckling does not take place. (Edited author abstract). 2 Refs.

## Stresses

**091821 MEASUREMENT OF THE INTERFACIAL STRESSES IN ROLLING USING THE ELASTIC DEFORMATION OF THE ROLL.** A new method to measure the frictional stresses and normal pressure in the roll gap during cold rolling, and experimental verification of this new method, are presented. The method overcomes many of the shortcomings of pin-type sensors. The elastic deformation of the roll itself is measured with strain gages, and is used to calculate the stresses between the sheet and the roll. Since no modification of the roll is necessary, the deformation process is undisturbed by the measurement. Mechanical isolation of the sensor is unnecessary. The mathematical procedure used to calculate the normal pressure and frictional stresses from the measured strains explicitly acknowledges that these strains are the result of the entire distribution of pressures and shears in the roll gap. (Edited author abstract) 34 refs.

**091825 ALGOMA'S NEW NO. 2 SEAMLESS MILL: THE PROCESS AND ITS CAPABILITY.** Algoma's new No. 2 seamless mill represents the latest in tubemaking technology. Main components include: a rotary hearth furnace; a hot mill consisting of a pierce, retained mandrel mill and stretch reducing mill; as well as extensive finishing and inspection facilities. There is a fully integrated computerized control system which includes the individual tracking of each piece of pipe during manufacture. Algoma's No. 2 seamless tube mill, conceived in 1979 to provide a broader range of pipe products from 1.9 to 123/4 in., was placed in operation in 1986. Preliminary results during start-up have confirmed that performance is well within API specifications with further improvements achievable as practices and procedures are refined. (Edited author abstract) 1 ref.

**091826 NEW STRETCH REDUCING MILL AT ALGOMA.** A 22-stand stretch reducing mill installed as part of Algoma's new No. 2, 303,000-tonne/year seamless tube mill produces 1.9 to 7.0-in. tube from a single shell size. A wall thickness control system is installed that increases product yield by 4 to 5% as well as a heavy end control system that reduces crop losses by approximately 15%. Other features include a variable group drive through differential drives, a 2-motor drive with one motor only influencing elongation and an automated quick stand change system. (Author abstract)

**091827 CROSS-ROLLING MILL AS A PIERCING UNIT - DEVELOPMENTS DURING THE LAST 15 YEARS.** In the hot manufacture of seamless tubes the piercing of the billets is carried out mainly on cross-rolling mills. Up to about 1970 the Stiefel-type mill with guide shoes was the most important of the cross-roll piercing mills. In 1972 the Diescher-type piercing mill was introduced, the main feature of which is the vertical arrangement of the rolls with horizontally arranged guide discs. This mill set new standards in respect of piercing performance. At the beginning of the eighties, the cone-type piercing mill with horizontally arranged rolls experienced a renaissance. The technological advantages of the cone-type piercing mill are the high elongating capability, the size flexibility and the capability of piercing high-alloy steels. In order to combine the technological possibilities of the cone-type piercing mill with the design advantages of the Diescher-type, a new cone-type piercing mill, one employing a vertical roll arrangement, has been developed. (Author abstract)

**091828 PROFILOGRAPH TO MEASURE WEAR OF THE TUBE-PIERCING MANDRELS.** The ability of tube production equipment - particularly tube piercing mandrels - to retain their shape for a long period of time determines the quality of the inside surface of the pierced shell, the productivity of the mill, and the cost of the product. The profilograph normally used to copy the mandrel profile and compare the copy with the original profile to determine the degree of wear requires the mandrel to be removed from the mill. This shortcoming is eliminated in the profilograph developed by the Gruzinsk Polytechnic Institute. This profilograph can be used directly on the mill during brief stoppages.

Mogil'ner, I.Yu. (Gruzinsk Polytechnic Inst, USSR); Berishvili, T.K.; Khundadze, E.N. *Metallurgist (USSR)* v 31 n 3-4 Mar-Apr 1987 p 67-68.

**091829 MODERNIZATION OF THE FEED MECHANISM OF A PILGER MILL.** The quality of tubes rolled on a Pilger mill and the productivity of the mill itself depend directly on the absolute value and stability of the angle of inclination of the shell during rolling, which in turn depend to a large extent on the design of the tilting mechanism. To eliminate wear problems, the authors designed a new manipulator. This design of manipulator precludes generation of an axial component of pressure from the air compressed in the piston chamber and acting on the thrust element of the drill. The design also prevents wedging of the drill in the nut. This reduces wear of the nut and drill and enhances the speed and performance of the air cylinder.

**091830 RASPODJELA BRZINA U ZONI DEFORMACIJE I PRORACUN BROJA OKRETAJA PRI KONTINUIRANOM TOPLOM VALJANJU CIJEVI NA IZVLACNO-REDUCIRNOM STANU.** [Speed Distribution in the Deformation Zone and Calculation of Number of Revolutions at Continuous Hot Rolling of Tube on SRM]. The speed calculation and distribution in the deformation zone at seamless tube rolling on a stretch-reducing mill (SRM) have been elaborated. By regulating the rolling speed the required reductions of cross-sectional surface and tube wall thickness are obtained. On the basis of the calculated speeds, rolling has been performed. The analysis of the results shows that there are small deviations which can be corrected by changing the position of the radius of rolls. (Edited author abstract) 7 refs. In Serbo-Croatian.

**091831 IMPROVING THE ACCURACY OF CASING ON A TUBE-PRODUCTION UNIT WITH PILGER MILLS.** During the XI Five-Year Plan, the Ural Scientific Research Institute of the Tube Industry collaborated with the Severskii Pipe Plant to develop a set of control and measurement procedures designed to increase the accuracy of casing made on model 168-325 tube production units with Pilger mills. The work was done to increase the accuracy of tube wall thickness and increase the straightness of the generatrix. The problem of increasing tube accuracy was solved by optimizing the deformation regimes and by developing and introducing new roll passes and methods of pass adjustment on the Pilger mill, sizing mill, and straightening machine. To increase wall thickness and tube diameter accuracy a pass system which reduces the longitudinal variation of wall thickness was developed.

**091836 AMELIORATION OF THE EFFECTS OF REDUNDANT SHEARING IN 3-ROLL OBLIQUE TUBE ELONGATION BY MEANS OF CRHS-DESIGNED PASSES.** In rotary tube-making operations, the presence of strains is reflected in a differential axial wall shearing (longitudinal), circumferential tendency to lap forming, wall caviting, and distortion of structure due to tube twisting when it is compensating for slip between the rolls. Tubular wax and lead specimens were elongated in a 3-roll oblique system to estimate the incidence of unnecessary macroshear strain, and the correlation between force and torque parameters and the redundancy of the system. The effect of pass geometry on the material response was tested against the conditions created by theoretical roll profiles designed in accordance with the CRHS concept and those produced by standard industrial passes. **091837 THEORETICAL ANALYSIS OF SHAPE OF POLYGONAL TUBE FORMED BY FORM ROLLING.** Theoretical study has been made to confirm shapes of polygonal tubes formed by the form rolling in which a round tube is rotated between some rollers. A geometrical shape that can rotate touching with all rollers without deformation was analyzed. The relation between the number of rollers  $m$  and the number of sides  $n$  of a

rotatable polygonal shape was derived to be  $n = mp \pm 1$ . The shape was described by a simulation of movement of rollers around a fixed imaginary polygon. The simulation gave a shape very similar to that of a tube formed practically. (Author abstract) 3 refs.

Asakura, Kenji; Tsuda, Hiroshi; Kohzu, Masahide; Ozaki, Shinji. *Bull Univ Osaka Prefect Ser A* v 36 n 1 1987 p 11-20.

**091838 EFFECT OF FORM ROLLING CONDITION ON THEORETICAL SHAPE OF FORMED POLYGONAL TUBE.** A study has been made to clarify the effect of working condition on the theoretical shape of polygonal tube formed by the form rolling in which a round tube is rotated between some rollers. The equation of a closed curve was derived, which represent a rotatable polygonal shape when calculative conditions are suitable. Then, the calculative conditions were analyzed and transformed into the practical working conditions: pre-deformation ratio  $\delta$ , tube diameter  $R_t$  and roller diameter  $R_r$ . The working conditions were represented as  $\delta-R_t/R_r$  diagram, which indicates polygonal shapes rotatable theoretically. The working conditions to obtain the theoretical shape similar to the shape of formed tube agree well with the working conditions in the practical forming. (Author abstract)

**091840 MANDREL MILL HYDRAULIC SCREW-DOWN CONTROL.** Mandrel mill hydraulic screwdown control was installed at the Kainan Steel Tube Works of Sumitomo Metal Industries, Ltd. in July, 1985. The purpose of the control is to preform tube ends in a thin tapered form. By preforming the tube ends, it is possible to cancel the end thickening in the reducer and reduce the length of crop losses. The analysis of variations in inter-stand tensions when end thinning control is carried out and the methods of roll speed control to prevent these variations are discussed. The causes of wall eccentricity in end thinning control and its countermeasures are described. The computer control system installed at the Kainan Steel Tube Works is presented. (Author abstract). 5 Refs.

**091841 INCREASE IN PROCESSING PLASTICITY OF DEFORMED METAL AFTER COLD PERIODIC ROLLING OF TUBES.** A description is given of the two-array and roll-roller methods developed in the All-Union Research Institute for the Tube Industry (VNITI) for the periodic rolling of tubes which enable the processing plasticity of deformed steels (corrosion resistant and alloy steels) to be increased by factors of 2-2.5. Use of these methods makes it possible to practically halve the production cycle time for smaller than 10 mm dia. cold deformed tubes in corrosion resistant and alloy steels and

alloys. This presents the possibility of raising pipe production by 40-50 percent for the same work areas. (Author abstract). 2 Refs.

## USSR

**091842 IMPROVEMENT OF ROLLED PRODUCT SHAPES.** Research in the Petrovsk Iron and Steelworks established the possibility of lowering the metal consumption of various rolled structural shapes (H-beams, channels, trough shaped sections, Z-sections, etc.) by 12-20% without lowering their bearing capacities. This is achieved by redesigning the shapes in such a way that parts of the volumes of the lightly loaded elements of the shape are transferred to those elements requiring reinforcement. A number of lightened rolled product shapes have also been assimilated on the section rolling mill. (Edited author abstract) 3 refs.

**091846 PLATE ROLLING MILL EXPANSION AT DILLINGER HUETTENWERKE.** The present article describes the design of the rolling mill at Dillinger Huette put into operation in 1973 as well as special features of erection, commissioning and past operating experience.

The new 5.5 m stand can be used both as a roughing and finishing stand. When being used as a roughing stand, longer and heavier concast slabs may be utilized. When being operated as a finishing stand, plates up to 5.2 m wide can be rolled as well as 64 in. large tube plates. With these facilities the mill is the only rolling mill outside Japan affording such great potential. (Edited author abstract)

Weber, Friedrich (Aktiengesellschaft der Dillinger Huettenwerke, Dillingen, West Ger); Oswald, Werner; Engel, Manfred; Kopf, Gerhard. *MPT Metall Plant Technol* v 10 n 5 1987 7p between 44 and 53.

**091847 NEW 20" SEAMLESS TUBE MILL.** In the course of the past years the Bromford Tube Works of the British Steel Corporation has been completely modernized. The elongator has been replaced by a Mannesmann rotary piercer. Two new cutting-off machines have also been installed. The most challenging part of the modernization project was the replacement of the pilger mill stand, pinion gearbox, hot saw, sizing mill, cooling bed, and straightening press. The installation of a completely new designed pilger mill overcame the disadvantages of the conventional pilgering process. Especially the introduction of continuously cast round material with direct piercing will result in a new breakthrough for the hot pilger mill. (Author abstract)

**091849 L'USINE SIDERURGIQUE A PRODUITS PLATS AU XXIEME SIECLE.** [Manufacture of Flat Products for the 21st Century]. A picture of the flat product steel plant of the 21st century is presented. On the one hand, integrated plants working continuously with such features as direct rolling and schedule-free rolling but making the best use of today's technology are likely to produce a large part of the world's steel. On the other hand new technologies are emerging, especially in the field of thin product, casting and rolling on compact mills. These developments may result in more compact plants, either mini-mills or integrated mills. (Edited author abstract) 41 refs.

Birat, J.P. (IRSID). *Cah Inf Tech Rev Metall* v 84 n 11 Nov 1987 p 773-788.

**091850 MEDIUM-SECTION MILLS FOR FUTURE DEMANDS.** This paper deals with the production process and optimization in rolling mills. Some of the topics discussed include high-capacity mills, steel mills, and small-scale production mills. Other topics covered include continuous finish-rolling and the effect of market conditions on production.

Feldmann, Hugo (SMS Schloemann-Siemag Aktiengesellschaft, Dusseldorf, West Ger); Mueller, Hubert. *MPT Metall Plant Technol* v 11 n 1988 6p.

**091851 FUNDAMENTAL STUDIES FOR APPLICATION OF NEW COMPACT MULTI-REDUCTION MILL.** A new compact multi-reduction mill (NCM) which can substitute one stand for two or three stands in a cold tandem mill has been developed. This mill is based on three-pass rolling in one stand and enables a 70% reduction in thickness in the cold rolling of mild carbon steel. The rolling experiments and numerical calculations

showed that strip-pulling-out type rolling was more suitable than strip-enveloping type rolling and gave excellent characteristics in rolling lubrication, roll cooling and heat scratch prevention. (Edited author abstract). 7 Refs.

**091852 ROLLING CHARACTERISTICS OF NEW COMPACT MULTI-REDUCTION MILL.** In order to achieve reduction over 70 percent in one cold rolling stand, the three-gap rolling method has been investigated. The new compact multi-reduction mill (NCM) consists of four work rolls arranged vertically in one housing and the strip is threaded through three roll gaps. A stable rolling condition has been accomplished by regulating the tension, roll speed difference and rolling force. The number of work rolls to be driven, conditions to realize the optimum inter-gap tensions, and the position of the neutral points have been investigated theoretically. The rolling force, torque, tensions, forward slip, rolling energy, and optimum rolling conditions have been investigated experimentally. Practical applications for tandem cold mills and reversing cold mills are discussed. (Edited author abstract). 5 Refs.

**091854 AUTOMATISIERUNG DER VORSTRASSE EINER BREITBANDSTRASSE.** [Automation of the Roughing Train of a Wide Strip Mill]. A process computer for the control of the roughing mill has been installed at Voest-Alpine AG in Linz. All the existing mechanical and electrical equipment has remained unchanged, and the adaptation and expansion steps taken in terms of automation and measuring technique were also reduced to a minimum. Commissioning took place virtually under running operating conditions of the mill. The project was completed at the beginning of 1986, and the initial operating results show that the envisaged objectives have been achieved. (Author abstract) In German.

Langer, Rupert (Voest-Alpine AG, Linz, West Ger); Pichler, Rudolf. *Stahl Eisen* v 107 n 22 Nov 2 1987 p 67-70.

**Bearings** See Also LUBRICATING OILS—Testing.

**091855 SPHERICAL ROLLER BEARINGS WITH-STAND OPERATING DEMANDS AT QUANEX MILL.** Spherical roller bearing pillow blocks are meeting performance demands under rigorous operating conditions at the 2-year old Quanex MacSteel mini mill at Fort Smith, Ark. Installed on eight Birdsboro roller conveyor tables that move hot steel billets from a rotary-type continuous caster to a cooling bed or through a reheating

furnace, the heavy-duty bearings have performed well around the clock on a 5 and 6-day weekly schedule, despite scale and high temperatures. Qualex MacSteel produces two types of high-quality specialty steel products at the Fort Smith mill.

Anon. *Iron Steel Eng* v 65 n 1 Jan 1988 p 60.

**091856 LOAD DISTRIBUTION IN ROLLING BEARINGS AND STRESSING IN THE ROLL CHOCK OF A ROLLING MILL.** A study was made of the effect of preloaded chocks in rolling mills on the load distribution in the bearings. According to the results obtained by finite-element calculation and the FAGT240 program, no unreasonably high additional loads are generated in the rolling bearings of preloaded chocks. The stresses generated in the chock are permissible. The chock deformations were measured. The measured results coincide to a large extent with the calculated results. 6 refs.

Schlereth, Werner (FAG Schweinfurt, West Ger). *Ball Roller Bear Eng* 1985 p 28-32.

**091857 REDUCED COST AND MAINTENANCE FOR ROLLING MILL DRIVE SHAFTS - SPLIT CYLINDRICAL ROLLER BEARINGS INSTEAD OF SLIDING BEARINGS.** The work rolls of large four-high rolling stands are driven via universal joint drive shafts. Originally the drive shafts were carried in greased split sliding bearings. The service life of which was found to be very short, in spite of an excessive application of lubricating grease. It was therefore decided to convert from sliding bearings to cylindrical roller bearings, also of split design. The split cylindrical roller bearings have about the same dimensions as the sliding bearings so that the old housings can be re-used after some reconditioning work. The new bearings operate reliably; problems have not yet occurred. Maintenance cost and work and above all the grease consumption could be reduced to an acceptable level.

Engisch, Hans (FAG Wuppertal, West Ger); Rudloff, George. *Ball Roller Bear Eng* 1985 p 34-35.

## Belgium

**091858 INVESTMENT AT SIDMAR TACKLES FINISHING QUALITY.** Investment in finishing has been the priority at Belgian steelmaker Sidmar. The company has approved a five-year plan to meet the increasing quality requirements in the market for strip. In its hot strip mill several projects are being undertaken to improve customer service and to move towards schedule-free rolling. A new walking beam furnace will enable the mill to roll stainless grades for which its present furnaces are not suited.

## Computer Aided Manufacturing

**091861 RECHNERGESTUETZTE STICH-PLANOPTIMIERUNG FUER EIN 130/390 X 400 SCHWERMETALLQUARTO.** [Computer Aided Optimization of the Roll Pass Schedule for a 130/390 X 400 Heavy Metal Four High Stand]. A program system for computing and optimizing pass sequences for two-high and four-high cold strip rolling mills is presented (initialized BOSFEKUG). Handling and practice-relatedness of the software package is illustrated at a 130/390 X 400 four-high cold rolling non-ferrous heavy metals stand. The qualitative and quantitative effects achieved are worked out and underlined by selected data. (Author abstract) 8 refs. In German.

**Computer Applications** See Also ROLLING MILL PRACTICE—Sheet and Strip.

**091862 RECHNERGEFUEHRTES THERMOMECHANISCHES WALZEN IN GROBBLECHSTRASSEN.** [Computerized Thermomechanical Rolling in Heavy Plate Mills]. In order to maintain a specified temperature range in thermomechanical rolling the rolling process has to be interrupted once or several times for the cooling of the rolled piece. The intervals between passes are used to roll further plates, i.e. multipiece rolling process. For the control of the forming and waiting phases resulting from the temperature and acceptance specification Siemens AG has developed an automation system, which determines the optimum number of passes within the rolling phases with the aid of the function rolling schedule computation. The waiting times between the forming phases are calculated by means of a temperature model. The program block image establishes a mapping of the mill assignment within the automation range. Only in this way is it possible for the computer to ensure an optimized control of the rolling process. (Edited author abstract) In German.

## Computer Simulation

**091864 SIMULATION PROGRAM FOR MILL SETTING OF HOT TANDEM MILLS.** A simulation program for hot tandem mill threading has been developed to estimate the mill setting system. Inputs to the program are the entry thickness, temperature of rolled stock, and mill setting values at each stand. Outputs are the strip thickness, the rolling force, strip temperature of each stand, and inter-stand strip loops. The calculated

threading conditions are displayed on a graphics display terminal. (Author abstract) In Japanese. 3 refs.

**Control** See Also METAL FORMING—Bending; ROLLING MILL PRACTICE—Bars; ROLLING MILL PRACTICE—Tube.

**091865 PROFILE CONTROL OF HOT ROLLED STRIP BY WORKING ROLL SHIFTING (K-WRS) MILL.** A new type of rolling mill has been developed that improves transverse gage profile and flatness of hot rolled strip as well as permitting schedule-free rolling. The concept, which has been applied to a number of hot strip mills, involves the side shifting of work rolls that are tapered at one end only. A mathematical model for predicting strip profile has been developed and optimum operation and automatic profile control have been established. 12 refs.

**091866 MINIMUM TENSION CONTROL IN FINISHING TRAIN OF HOT STRIP MILLS.** A minimum tension control (MTC) system has been installed on a 2000-mm wide hot strip mill to reduce maintenance and operating cost associated with interstand loopers. Superimposed on the main electrical drive control system, it generates the correct cascade speed setpoints to control interstand material flow based on tension-dependent changes in rolling torque. The technology required to implement MTC is reviewed in this article together with the results of measurements obtained during operation.

**091868 AGC SYSTEM FOR COLD STRIP MILL WITH A.C. MOTOR DRIVEN SCREWING DOWN INSTALLATION.** This paper presents a method of using an AGC system with an adaptive gaugometer. Based on rolling pressure data sampled in line, this new system estimates the parameter of presaging pressure-model by recursive least square identification algorithm, forecasts the pressure of the stand itself, and determines the magnitude of screwdown control according to minimum variance control law. This paper also presents methods used to realize AGC in unfavorable conditions by using A.C. motor driven screwing down equipment as actuator of the controller. These methods were studied by digital stimulation on cold strip mills to overcome the gauge disturbance caused by skid marks and entry thickness difference, and have been used in the 350mm three-stand tandem cold mill in Shanghai No.10 steel works. (Edited author abstract) In Chinese. 6 refs.

**091870 DIGITAL CONTROL OF AN EXISTING 5-STAND TANDEM COLD MILL.** Computerization of a tandem cold mill provides two main functions: process control and a supervisory role. Process control functions include interstand tension, screwdown operation and automatic gage control using delivery and entry stand x-ray gage deviations. Supervisory functions are orders and schedules, tracking through the mill and production information. The mill described is Ashland's 5-stand, 4-h tandem cold mill.

Lewis, Charles O. (Armco Inc, Ashland, KY, USA); Sturgill, Michael L. *Iron Steel Eng* v 64 n 11 Nov 1987 p 20-24.

**091871 ANALYSIS AND CONTROL SYSTEMS FOR SHAFT VIBRATION IN STEEL ROLLING PROCESSES.** In recent years, the authors have been endeavoring to revamp steel rolling processes by realizing continuous and synchronized production between two processes in order to achieve higher quality of products. In cold and hot tandem mills or continuous annealing process lines, which required high response and high accuracy to the motor control system, the authors encountered troubles with shaft vibrations caused by interaction between mechanical and electrical control systems, and developed a new power drive technique which was effective in solving the problems. And authors were able to understand the influence of all the digital thyristor motor drive system and the cross current type cycloconverter drive system on the shaft vibration problem through computer simulation analyses and experiments. As a result, the following were found effective in suppressing shaft vibrations: (1) to apply a digital filtering method to speed feedback, (2) to control a speed control loop in high speed sampling time and high accuracy calculation, and (3) to apply the modern control theory. (Author abstract) 3 refs.

**091872 SENSOR-TYPE AUTOMATIC STEERING CONTROL SYSTEM FOR ROLLING MILL - 1ST REPORT THEORETICAL ANALYSIS AND EXPERIMENTAL RESULTS.** During rolling operation, the rolled strip is often driven rapidly to one side and, as result, the strip breaks on the work rolls are damaged. This unstable behavior is caused by horizontally asymmetrical factors of rolling conditions. To control this lateral instability, IHI has developed a new type of automatic steering control (ASC) system, the major feature of which is the installation of a sensor detecting the lateral movement of the rolled strip. This paper gives a theoretical analysis and experimental results of the new ASC system which clarifies the system far more effective than the conventional ASC system. (Edited author abstract) 3 refs.

Kuwano, Hiroaki (IHI, Tokyo, Jpn); Takahashi, Norio. *IHI Eng Rev (Engl Ed)* v 19 n 4 Oct 1986 p 152-157.

**091873 SENSOR-TYPE AUTOMATIC STEERING CONTROL SYSTEM FOR ROLLING MILL - 2ND REPORT: DEVELOPMENT OF HOT STRIP STEERING SENSOR.** Reference is made to a previous

paper in which a new type of automatic steering control system was proposed, the major feature of which is the installation of a (referred to as 'steering sensor') detecting lateral movements of the rolled strip. This paper gives a brief description of the newly developed hot strip steering sensor. Field experiments have confirmed that the sensor can detect movements of the hot rolled strip rapidly and precisely. (Edited author abstract) 5 refs.

**091874 MICROPROCESSOR-BASED DISTRIBUTED CONTROL SYSTEM INSTALLED AT RAVENSCRAIG.** British Steel's Ravenscraig plant, near Glasgow, Scotland, has recently undergone an extensive modernization program. A key element of the program was major modifications on two of three reheating furnaces and installation of a sophisticated MAX 1 distributed control system at the hot strip mill. Ravenscraig is moving rapidly into information technology - revamping the hot mill control system is just part of an overall plan. It was important that the system be fully and effectively operational from the outset.

**091883 INGENIEURAUFGABEN BEIM BAU UND IM BETRIEB NEUZEITLICHER AUTOMATISIERTER WALZANLAGENTECHNIK.** [Tasks for the Engineer for the Construction and Operation of Modern Automated Rolling Mill Technique]. Modern rolling plants are characterized by a high degree of automation. There are high demands upon throughput capacity, quality and reliability. During design of such plants, process and system analyses have to be carried out. The interaction between electrical systems and mechanics and the technical process are to be determined and the structural design is to be optimized by simulation. To achieve high operational safety and reliability, a determination of stresses, deformations and service life parameters of the structural elements is of utmost importance. (Author abstract) 14 refs. In German.

Guericke, Wilhelm (Technische Univ, Magdeburg, East Ger); Becker, Hans. *Neue Huette* v 33 n 4 Apr 1988 p 128-132.

**091884 HOCHEFFEKTIVES FEIN- UND MITTELSTAHLWALZWERK FUER QUALITAETSTAEHLE.** [High Efficient Small and Medium Section Rolling Mill for Quality Steels]. The largest rolling mill ever supplied by SKET is described in this article. Involved in the metallurgical complex recently built at Oskol (USSR), the small-and-medium-section mill for the manufacture of high-grade steels represents the final process stage of a closed metallurgical cycle. The mill's designed capacity amounts to one million metric tons of finished material, the share of small and medium section steels being approximately equal. Owing to the great variety of processes and equipment solutions used, the plant represents the latest rolling mill standards. Thus, the hot charging of feedstock, low-temperature rolling, almost continuous rolling at maximum furnace capacity and an immediately following annealing process utilizing the rolling heat will among other hightech standards result in good economic effects as far as the prospective user is concerned. Further distinct characteristics are the mill's electrical equipment based upon memory-programmable controls as well as a comprehensive automation system. (Author abstract) 7 refs. In German.

**091886 APPLICATION OF 3-ROLL TECHNOLOGY FOR ROLLING SPECIALTY ROD AND BAR PRODUCTS.** Increasing quality demands to be met by specialty steel rod and bar products can be economically achieved with 3-roll mill stands. In addition to improved surface quality, closer dimensional tolerances and a homogeneous structure, operating advantages reported include higher yields, higher mill availability and lower energy consumption. The use of 3-roll technology for the production of quality and specialty steels avoids many of the problems that are typically encountered in a 2-high rolling operation. Also the processing costs are lower. The layouts of several mills are shown.

**091891 DEVELOPMENT AND INTRODUCTION OF THYRISTOR AND UNCONTROLLED CONVERTERS FOR MAIN ELECTRIC DRIVES OF NON-REVERSING ROLLING MILLS.** Thyristor and uncontrolled converters installed on the main drive of some Soviet non-reversing rolling mills and their performance are described. The Yuvenergohermet Production and Technical Enterprise has developed and, jointly with the Taganrog, Donetsk, and Sulino iron- and steelworks, and the K. Liebknecht and Azerbaidzhan tube rolling works, introduced thyristor (2000-7200 kw, 3 sets) and uncontrolled (550-5150 kw, 12 sets) converters with a total installed capacity of 59.5 Mw. Their special features are compared. (Edited author abstract)

Osadchii, V.G. (Yuvenergohermet Production & Technical Enterprise, USSR); Alekseevich, V.A. *Steel USSR* v 17 n 7 Jul 1987 p 337-338.

**091892 EXPERIENCE WITH a-c CYCLOCONVERTERS FOR HIGH-HORSEPOWER MILL DRIVES.** Rolling mill stands require extremely high drive powers. At the same time, high demands are placed on the control dynamics and peak load capability of these drives. By using a static cycloconverter with the Siemens Transvektor control, excellent performance characteristics can be obtained while insuring economic operations. The ac cycloconverter drives provide reductions in operating costs due to higher efficiency (approximately 4%) compared with dc drives and insignificant inspection and maintenance requirements. Applications have been made in blooming, plate, hot strip and cold mills. The discussion covers power factor, harmonics and typical installations. 6 refs.

**Equipment** See Also ROLLING MILL PRACTICE—Control Systems.

**091894 MEANS OF MECHANIZATION IN ROLLING-MILL PRACTICE.** Fork-type manipulators, positioned between the roller conveyors, are used on intermediate and section mills to tilt the semifinished product or section as it moves from one stand to the next. However, the manipulator cannot handle pieces that are bent lengthwise or twisted; the piece must contact the manipulator at a certain spot, with its front end first. The article describes a design of manipulator which eliminates these problems and a roller conveyor which places the rolled product into containers.

Gevlich, G.I. (Makeevka Metallurgical Combine, USSR). *Metallurgist (USSR)* v 31 n 7-8 Jul-Aug 1987 p 260-262.

**091895 MANIPULATOR FOR A SQUARE SEMIFINISHED PRODUCT.** A manipulator for handling square semifinished products was installed in front of a 550 roughing stand. Installation of the manipulator has improved the gripping of the square in the rolls of the mill stand. The thrust blocks and their stationary supports were set at a 120° angle in the manipulator relative to the base. The surface of the supports in contact with the square was made in the form of an arc. The article describes how the square is handled.

Goncharov, V.I. (Chelyabinsk Metallurgical Combine, USSR); Sidash, A.I. *Metallurgist (USSR)* v 31 n 7-8 Jul-Aug 1987 p 263.

**091896 NEW COMBINATION HOT LEVELLER FOR THIN AND THICK PLATE.** Recent development in thermomechanical control process (TMCP) in plate mills has made it possible to produce steel plates with higher strength and toughness. However, the problem of poor shapes which cannot be flattened by the conventional

hot leveller has arisen. In order to cope with this problem, Sumitomo Metal Industries, Ltd. has developed a combination hot leveller in Kashima Steel Works.

**091903 WORK ROLL SHIFT MILL FOR HOT ROLLING.** Recent progress in hot strip and plate rolling for energy saving and improved product quality and yield includes hot charge rolling and hot direct rolling. New work roll shift mills by Hitachi have roll bending and shifting mechanisms which are controllable according to rolling methods. The work roll shift mill provides high accuracy of crown control and minimization of edge drop.

## Lubrication See Also STEEL SHEET—Rolling.

**091904 ROLLING LUBRICANTS IN TODAY'S ENVIRONMENT.** The demands for improved quality and performance from the steel industry have increased in recent years. New technology for rolling lubricants and ancillary process fluids has been developed. These developments enable higher speeds, bigger reductions and cleaner strip to be produced. They also reduce the problems encountered when rolling concast strip and allow the use of chrome/alloy rolls. Theory and practical results are presented. Controlled particle size emulsification is discussed. 3 refs.

## Machinery

**091905 CALCULATION OF DYNAMIC TORQUE AND LOSS OF STRETCHING FORCE FOR COILERS.** The dynamic torque and the loss of stretching force for coilers have been considered by the designer in order to satisfy coiling constant-stretching force. It must be calculated exactly, especially when put under the use of computer control. In this paper, the formula of calculation of dynamic torque and loss of stretching force for coilers is established by using two examples. (Author abstract). 3 Refs. In Chinese.

## Maintenance See Also ROLLS—Spalling.

**091906 SAW SETUP SURFACES CONTINUOUS CASTER ROLLS.** An exacting and precise specialty, the repair and maintenance of continuous caster rolls for steel mills has become an integral part of Millcraft Products' operations. The operational condition of these rolls is extremely critical to the final shape of the product. To withstand the high temperature and corrosive environment of the water used to cool the steel slabs, the continuous casting rolls typically are made from a high-chromium alloy steel. These alloy steel rolls provide excellent corrosion and oxidation resistance, superior metal-to-metal wear resistance and good thermal fatigue property values. Periodic maintenance of caster rolls is required to ensure a high-quality finished product from the steel mill. The worn rolls are preheated to prevent excessive buildup of internal stresses, which may cause cracking during welding. The company uses Lincoln Electric's Tiny Twinarc submerged arc welding system to buildup and hardface the rolls.

**Mathematical Models** See Also ROLLING MILL PRACTICE—Bars; ROLLING MILL PRACTICE—Cold Rolling; SHEET AND STRIP METAL—Rolling.

**091907 MATHEMATICAL MODELS FOR COMPUTER CONTROL OF HOT ROUGHING MILL OF ALUMINUM.** Mathematical models to estimate the rolling force P and the rolling torque G of hot roughing mill of aluminum were developed. These models consist of equations to calculate the rolling force function  $Q_p$ , the torque arm coefficient  $\lambda$  and the mean flow stress  $K_{fm}$ . The equation of  $Q_p$  and  $\lambda$  are derived empirically by analyzing the rolling data. The equation of  $K_{fm}$  is based on the empirical expression of the experimental data by complastometer. Almost satisfactory accuracy is achieved in estimating P and G. The calculating method to obtain the pass schedule in the restrictions of rolling force, rolling torque, angle of biting etc. was developed. The total number of passes reduces and the productivity of roughing mill for aluminum alloys increases by using this new pass schedule. (Author abstract) In Japanese. 10 refs.

## Mexico See IRON AND STEEL PLANTS—Mexico.

**Modernization** See Also ROLLING MILL PRACTICE—Cold Rolling.

**091908 MODERNIZATION OF A TANDEM COLD MILL WITH DISTRIBUTED DIGITAL CONTROL.** A 4-stand tandem mill modernization includes repowering, automatic controls, and automatic tension and gage control. The mill setup system and dynamic speed analysis procedure are described. The mill modernization described is designed to improve productivity and product quality with a minimum of mill downtime.

Smith, Andrew W. (Westinghouse Electric Corp, Pittsburgh, PA, USA). *Iron Steel Eng* v 64 n 10 Oct 1987 p 45-49.

**091909 USE OF UNDERGROUND CONSTRUCTION METHODS DURING THE RECONSTRUCTION OF METALLURGICAL SHOPS.** Chelyabinsk Specialized Shaft Construction Administration No. 6 of the Vostokshakhtoprokhodka Trust of the Soyuzshakhtoprokhodka Industrial Association was created in 1978 to conduct work on reconstruction in existing plants. It has recently completed several projects involving the construction of underground facilities at the Chelyabinsk, Magnitogorsk, and Nizhny Tagil metallurgical combines. The article describes the reconstruction of the hot strip mills and associated structures.

Baranov, L.P. ('Vostokshakhtoprokhodka' Trust, USSR); Severinov, I.A.; Dolinin, P.S. *Metallurgist (USSR)* v 31 n 5-6 May-Jun 1987 p 141-143.

**091910 MODERNIZATION OF A HEAVY SECTION MILL AT THE EGYPTIAN IRON & STEEL CO.** The Egyptian Iron & Steel Co. placed an order with Krupp to supply services and equipment to modernize the blooming and section mills at the Helwan works. Installation of combination universal/2-h roughing and finishing stands with movable housings permits efficient production of a wide range of sections (parallel flange beams, rails, angles, channels and bars). Universal or 2-h roll sets installed in a spare stand minimize mill downtime and optimize productivity.

El Sherbini, Ziad (Egyptian Iron & Steel Co, Cairo, Egypt); El Dahab, Hassan Abou; Madersbach, Wolfgang; Rekos, Werner. *Iron Steel Eng* v 65 n 4 Apr 1988 p 29-35.

**091911 FURTHER MODERNIZATION OF THE COLD WIDE STRIP MILL AT STAHLWERKE PEINE-SALZGITTER AG.** In order to improve the product quality and reduce the energy consumption the company undertook an extensive modernization project embracing the areas of pickling, the tandem mill, batch annealing, the temper mill and the finishing shop in their cold wide strip mill. The article describes the conversion measures and their operational effects. The continuous pickling plant was equipped with 3 flat pickling baths and is now computer controlled. Detection of defects is assisted by automatic surface inspection. The tandem mill was mechanized and automated, being provided with a process control system, a new gauge control system and, as the fifth stand, a 6-high stand with flatness control and its own emulsion circuit. The annealing plant is at the moment being converted to high-convection furnaces. (Edited author abstract)

Koehler, Gerhart (Stahlwerke Peine-Salzgitter AG, Salzgitter, West Ger). *MPT Metall Plant Technol* v 11 n 2 1988 7p.

**091912 MODERNIZATION OF INLAND STEEL'S 56-IN., 4-STAND TANDEM MILL.** Modernization of a 1958 tandem mill has resulted in a facility with significant quality and productivity improvements. In-body gage deviation, for example, has improved from  $\pm 3\%$ , to less than  $\pm 1\%$ . Components of the program include conversion to hydraulic AGC on all stands; closed-loop shape control; roll bending; side-shift roll changers; and entry end modifications.

Ryba, Thomas C.; Hennes, James M.; Mills, Dennis R. *Iron Steel Eng* v 65 n 6 1988 p 17-23.

**091913 MODERNIZATION OF A SECTION MILL FOR THE EGYPTIAN IRON AND STEEL COMPANY.** The Egyptian Iron and Steel Company, Hadisob, contracted Krupp Industrietechnik to modernize the blooming, section and plate mills in its Helwan works. The report describes the work involved in modernizing the section mill, highlighting the approach selected and special technical features and requirements. (Author abstract)

Buch, E. (Krupp Industrietechnik GmbH, Duisburg, West Ger); Klute, F.; Rekos, W. *Tech Mitt Krupp (Engl Ed)* n 1 Apr 1987 p 35-44.

**091914 MODERNIZATION OF HOT STRIP MILLS.** After a pause of several years, hot strip mills

worldwide are beginning to pay renewed attention to project activities. The article concerns itself with the important modernization measures. These include the installation of walking beam furnaces with a lower hearth loading, reduction of the temperature to which the slab is heated, installation of a 4-high reversing stand in the roughing train with greater rigidity and high capacity drives, installation of an edger with a high width reduction and automatic width control, installation of insulation hoods between the roughing and finishing trains or the incorporation of a coilbox, conversion to a larger transfer bar thickness by the installation of a heavy crop shear, expansion of the rolling program through increasing the efficiency of the finishing train, installation of hydraulic screwdown as well as of profile and flatness control in the finishing train, laminar cooling between finishing train and coiler, downcoilers with hydraulically controlled wrapper roll retraction for greater coil weights and strip thicknesses, process automation, hot charging and direct rolling. (Edited author abstract). 7 Refs.

## Noise Abatement

**091918 KOERPERSCHALLDAEMMUNG UND IMMISSIONSSCHUTZ BEI FERTIGUNGSANLAGEN MIT ELASTISCH GELAGERTEN GROSSFUNDAMENTEN.** [Structure Borne Sound Insulation and Protection Against Immission in Industrial Plants by Elastically Embedded Large Block-Type Foundations.],

The paper refers about the design and the construction of the elastic bedding of a foundation for a rolling mill for Molybdenum sheets. Due to dynamic measurements at a smaller, but similar-type rolling mill and within an established mechanical model it is possible, to predict the expected loading conditions on the foundation. Thus it is shown, that an elastically embedded foundation is necessary to protect adjacent facilities against vibrations. Due to conceptional reasons elastic Polyurethane mats are used as vibration isolator. The layout of the foundation-isolation system is described in detail. Finally the results from field measurements, after completion of the foundation, are compared with calculated values from the design stage. (Author abstract). 17 Refs. In German.

## Ohio

**091919 LTV'S 84-IN. HOT STRIP MILL AT CLEVELAND WORKS.** Cleveland works is LTV Steel's largest steelmaking operation and the largest flat rolled complex in the U.S., based on hot rolled capacity. The mill is a combination of the former Jones & Laughlin plant on the west side of the river and the former Republic Steel facility on the east side. In addition to two coke plants on the east side, there are six blast furnaces (three operating); two 2-vessel BOF shops; one 2-vessel electric furnace shop; two slabbing mills; one continuous twin-strand slab caster; two hot strip mills, two tandem mills and three finishing mills. Some of the products include hot rolled bands and sheets, strip mill plate, cold rolled sheets, electrogalvanized sheets, preprinted sheets and cold rolled motor lamination steel produced in a variety of grades including high-strength low-alloy (HSLA), alloy and high carbon.

## Scheduling

**091923 TASK SCHEDULING ALGORITHMS FOR MULTIPROCESSOR REAL-TIME CONTROL SYSTEMS.** The computing load for the control of a steel rolling mill plant may be regarded as a group of tasks (each task is an individual program) such as setting of controlled variables and operation monitoring. The task group can be represented by a task graph, an acyclic finite directed graph because precedence relations exist among the tasks. Dynamic scheduling methods are proposed which are extensions of the developed static scheduling algorithms. Their efficiency in comparison with the deadline driven scheduling algorithm developed by Liu and others is shown. 8 refs.

## Tennessee

**091926 MIGHTY MILL TO DEFEND ALCOA'S CANSTOCK SHARE.** Alcoa wanted to fortify a leadership position in the booming canstock market, but needed more capacity as the demand for aluminum beer and

soft-drink cans accelerated during the late 1970s. For this reason the company upgraded a mill in Tennessee. Some major elements of the program include: a \$100 million modernization of the hot line, an automated materials handling system employing automatic guided vehicles (AGV), an electromagnetic ingot casting facility, computer-automated roll grinders, a new scalper, and two of the world's fastest aluminum strip shears.

Church, Fred L. (Modern Metals, Chicago, IL, USA). *Mod Met* v 43 n 11 Dec 1987 6p between p 10 and 24.

**091927 'WORLD'S MOST MODERN ALUMINUM CONTINUOUS ROLLING MILL'.** What Alcoa calls the world's most modern aluminum continuous rolling mill has gone on line at their Tennessee Operations near Knoxville. The \$150 million multi-stand, fully continuous cold mill is the keystone of a four-year, \$400 million effort to completely modernize Alcoa's 75 year old East Tennessee manufacturing complex. Tennessee Operations is dedicated to the manufacture of aluminum beverage can body sheet for can makers. The most modern features of the mill are the roll stock technology on the three-stand rolling mill and the instrumentation, computerization and predictive diagnostic capabilities of the 4 computers.

## Tools, Jigs and Fixtures

**091928 LOW-WASTE PROCESS FOR MANUFACTURING A PRECISION STAMPING TOOL.** The All-Union Correspondence Institute of Mechanical Engineering is developing a process for producing tools for tube rolling mills by precision hot stamping. The use of precision hot stamping of tube-milling tools permitted an increase in labor output by a factor of 9 and during mechanical treatment by a factor of 2-3 and reduced metal consumption 2- to 3-fold. During manufacture of bolts by stamping, owing to the increase in impact and fatigue characteristics of the metal, steel OKhN2F was replaced with the cheaper 30KhGSA. The cost of the stamped parts declined by a factor of 2-3. The economic effect from introducing the new process amounts to about 90 thousand rubles per year.

**Cast Iron** See Also PAPERMAKING MACHINERY—Rolls.

**091933 OPTIMUM IN-MOLD TREATMENT CONDITIONS FOR ROLLING-MILL ROLLS.** The treatment parameters and optimum conditions for the production of rolling mill rolls have been investigated. The in-mold treatment parameters were optimized by a series of experiments based on a Box-Wilson plan. The selected optimization parameters were the additive size analysis pouring temperature and the dissolution factor FR (the ratio between the pouring rate by weight and the cross-sectional area of the reaction chamber). The proposed parameters have been corroborated by trials at the Dnepropetrovsk Roll Foundry.

Skoblo, T.S.; Maslov, A.A.; Doluda, A.A.; Novikova, S.K. *Sov Cast Technol* n 6 1987 p 31-33.

**091934 METHOD FOR INSTALLING THERMOCOUPLES IN A MOLD.** The quality of cast rolls depends on the design and heat resistance of the mold components, the pouring conditions, and the metal cooling rate. This created a need for experimental studies of hardening of cast iron rolls cast in combined (shell-sand-clay) molds. The cast iron was poured at 1280-1320°C depending on the chemical composition and required hardness of the working layer. Production of individual heat-protected blocks for each thermocouple proved to be the most suitable method for conditions of a rolling mill. 1 ref.

Khrychikov, V.E.; Koteshev, N.P.; Efimenko, I.A. *Sov Cast Technol* n 9 1987 p 65-66.

**091935 CENTRIFUGAL CASTING OF ROLLS FOR WIDESTRIP MILLS.** An experimental batch of rolls for the 1680 mill has been produced at the Lutugino Roll Foundry. Preliminary trials have shown that centrifugally cast rolls weighing up to 10 tons can be made in the proposed machine with a variable axis of rotation using existing technology. The major difference between this

and other machines is the provision of radial thrust bearings in the mold supports. The design provides constant axial compression, and the mold is rotated by a system with conical mating surfaces.

## Corrosion

**091937 CORROSION FATIGUE TESTING OF SUCTION ROLL ALLOYS.** A broad correlation between crack growth rate and service performance has been found in the regime where the crack growth rates are low, provided the fatigue tests are performed in simulated white waters and large mean stresses are present. (Author abstract) 12 refs.

Yeske, Ronald A. (Inst of Paper Chemistry, Appleton, WI, USA). *Tappi J* v 71 n 3 Mar 1988 p 47-54.

**Defects** See Also ROLLING MILL PRACTICE—Bars.

**091938 SELECTING OPTIMUM INTERFERENCES FOR LARGE PRESS-FIT JOINTS TO SUIT THE PRODUCTION TECHNOLOGY.** With very large press-fit joints, the problem of choosing a suitable interference is especially difficult because of restrictions imposed by the production technologies employed. In particular, heat-treatment of very large parts can cause significant stresses. If the stresses caused by the interference fit are sufficiently high and the defects sufficiently serious, the sleeves can crack. Experience shows that brittle fracture of the sleeves occurs along the generating-line, i.e. in planes perpendicular to the maximum tensile stress. Consequently, it can be assumed that damage occurs as a result of normal fracturing. 8 refs.

Firsov, V.T. *Sov Eng Res* v 7 n 3 Mar 1987 p 25-27.

**091939 AUTOMATIC ULTRASONIC FLAW DETECTOR FOR ROLL SURFACE CRACKS (KARCS).** Recent demands for higher quality and productivity of rolled sheets have brought severe conditions in both hot and cold rolling, and troubles due to cracks on the roll surface often arise. To prevent such cracks from growing, early detection and removal of the flaws are necessary. An automatic crack detection system (KARCS) developed by Kanto Special Steel Works will meet these requirements. It is based on surface wave ultrasonic testing techniques.

**091941 METHOD FOR EVALUATION OF ROUGHING MILL ROLL DESIGN.** A method for the evaluation of the efficiency parameters of mill roll designs and rolling conditions in roughing mills has been proposed. The evaluation has been based on mill equipment utilization efficiency in terms of roll nip, equipment strength and drive rating. An algorithm and associate computer program have been developed for calculating the efficiencies. Method applications have been illustrated using comparative analysis of mill roll designs and rolling conditions for several roughing mills. (Author abstract)

**091942 IMPROVED DESIGN OF ROLLS FOR THE PIERCING MILL OF A PILGER UNIT.** There are certain features to the process of producing large diameter (up to 575 mm) tubes on the Pilger unit at the Chelyabinsk Pipe Plant. One such characteristic is the formation of triangles defects on the sides of the pipe during rolling. Investigations showed that the main shortcoming of the existing design for the work rolls is the fact that it is difficult for the shell to move away from the mandrel at the end of piercing. The formation of triangles associated with this problem was eliminated by a new roll design.

Getiya, I.G. (All-Union Correspondence Inst of Mechanical Engineering, USSR); Osadchii, V.Ya.; Shumilin, V.K.; Saf'yanov, A.V.; Lapin, L.I.; Logovikov, V.A.; Aver'yanov, L.A.; Leont'eva, I.N. *Metallurgist (USSR)* v 31 n 3-4 Mar-Apr 1987 p 59-62.

**091943 IMPROVED ROLL DESIGN ON A CONTINUOUS INTERMEDIATE MILL.** The continuous intermediate mill at the Chelyabinsk combine has 14 stands jointed into three continuous groups. The odd stands (5th through 13th) are vertical, while the remaining stands are horizontal. Rectangular (box) passes are used in the first eight stands, while diagonal (diamond - square) passes are used in the finishing group. The transition from box passes to passes with diagonal symmetry is accompanied by an increase in the tendency of the bloom to twist at the outlet of the first diamond pass and to buckle in subsequent stands. This problem was eliminated by improved roll design.

**091944 FRACTURE ANALYSIS OF THE SMALL-SIZED COLD MILL ROLL MADE OF GCr15 STEEL.** This paper deals with a systematic analysis of fractured GCr15 steel cold mill rolls with metallography. It is considered that most of the fractures of the rolls in this lot after machining and treatment, belong to the brittle fracture type at low cycle fatigue. The main cause of the fracture was that the root of the shaft shoulder is coarse in machining, and stress concentration existed in the right angular cutting corner, in which microcracks may be produced during quenching, and these become the fatigue sources. Secondly, due to an improper heat treating process, the carbide network still remained in the structure of products, which not only decreases fatigue resistance but also increases brittleness. By means of an advanced process, a lot of forging was machined and heat treated. As a result, the service life of rolls is increased by 10 times. (Edited author abstract) In Chinese.

**091945 STRESS ANALYSIS OF GROOVED ROLLS HAVING CLOSED PASSES AND DISCUSSION ON THEIR GROOVE SHAPES BY PHOTO-ELASTIC METHODS.** The stresses were analyzed by a three-dimensional photoelastic method and the cause of the breakage was studied. The effect of groove shapes on the stress distribution of the grooved roll was investigated by a two-dimensional photoelastic method. The breakage was caused by large mechanical working stresses. To prevent breaking of the grooved roll at a groove fillet, it is effective to make the diameter of the groove and collar as large as possible. (Edited author abstract) In Japanese. 12 refs.

**091946 SURVEY OF ROLL COVER FAILURES.** A survey is reported on roll cover failures in the Canadian pulp and paper industry. Statistics are presented on 225 rollcovers which failed prematurely between 1980 and 1985. These data are based on reports from 50 newsprint, pulp, board and fine paper mills. Most of the failures occurred on press rolls, and the most common mode of failure was covered disbonding. Some of the reasons for disbonding are briefly reviewed. (Author abstract) 6 refs.

## Heat Treatment

**091950 TRATAMENTO TERMICO DE ROLOS DE LINGOTAMENTO CONTINUO RECUPERADOS POR SOLDA.** [Heat Treatment of Continuous Casting Rolls Recovered by Welding]. The performance of the continuous casting rolls depends on their relative position in the continuous casting machine. Different mechanical stresses generate cracks and warpings, which adversely affect product quality. The substitution of weld surfacing by submerged arc cladding using stainless steel wire for a new low grade steel followed by a specially developed heat treatment procedure is shown in this paper, resulting in excellent roll performance and low cost. (Edited author abstract). In Portuguese. 5 refs.

Soares, David; Larangeiras, Jose Carlos; Almeida, Joaquim Nunes. *Metal ABM* v 43 n 356 Jul 1987 p 420-422, 424-425.

**091951 ELECTROCONTACT QUENCHING OF CAST-IRON ROLLS.** Studies were conducted on 500-mm-diameter rounds cut from cast iron (grade SPKHN-45) rolls. Analysis of the results makes it possible to recommend electrocontact quenching for surface strengthening of rolls. It increases the hardness of the working surface to HFC 45-50 to depths of up to 1.5-2.0 mm.

**091952 DEVELOPMENT OF SURFACE TREATMENT TECHNIQUES FOR PROCESS ROLLS IN STEELWORKS.** Studies on surface treatment techniques of process rolls, except for working rolls in iron and steel works, were carried out by taking account of the operating conditions. Welding materials of rolls used in the continuous casting process and hot rolling process were developed, which would particularly satisfy such properties as adhesion resistance, heat-check resistance and wet-corrosion resistance. It was found out that CrC cermet with a superior wear-resistance property at high temperature and the CoCrAlY alloy with a build-up resistance property were suitable for hearth rolls. Furthermore, it was found out that WC containing Ni self-fusing alloys were suitable for conductor rolls and WC thermal spray materials were suitable for rolls used in the cold rolling process. Reliability and long-life of various process rolls were improved by these new techniques. (Author abstract) 14 refs.

**091953 CASTING CLAD ROLLING-MILL ROLLS ON A STEEL CORE.** Two novel techniques have been developed and tested for the production of rolling mill with a hard wear-resisting outer layer on a ductile core. The shrinkage of the cast outer layer is provided for by (1) flattening tubular metal inserts or (2) by preheating a steel layer-separating tube which remains as the inner layer of a two-layer cladding. By supplying rolling mills with sets comprising a single core and 3-4 cladding units, it is possible to reduce alloy iron consumption by 60%, guarantee a specified working layer thickness and prolong roll lives by 30-40%. 3 refs.

**Spalling** See Also HEAT TREATMENT—Nitriding.

**091955 CAUSE AND PREVENTION OF SPALLING OF BACKUP ROLLS FOR HOT STRIP MILL.** The spalling on the surfaces of backup rolls is classified into two categories: excess rolling contact fatigue resulting from local wear and propagation of surface cracks generated by thermal shock in mill accidents such as squeezing and roll slip and incomplete removal of cracks in roll dressing. Factors for preventing the spalling phenomena are studied from experiments. The spalling tendencies are correlated with the carbon and chromium contents, areal fractions of carbides, and fracture toughness values of roll materials. To prevent spalling, it is necessary to control and improve the properties of roll materials and procedures of roll maintenance. (Edited author abstract) 7 refs.

**Steel** See Also ROLLING MILL PRACTICE.

**091956 EFFECTS OF DIFFERENCE IN ROLLER HARDNESS ON ROLLING CONTACT FATIGUE.** Rollers made from 0.45% carbon steel with hardnesses in the range of 190 to 500 HB were used as test pieces. The rollers were rotated under rolling with sliding conditions. The sum of the initial surface hardnesses of the rollers was made greater than the theoretical oil film thickness, in most cases. By measuring the duration of full EHL conditions, the friction coefficients, etc., it was clearly shown that the reason why an unexpectedly small hardness difference can cause pitting failure is attributed to the insufficient running-in which occurs when the hardness difference is greater than a certain limit. (Edited author abstract) 12 refs.

**091958 EFFECT OF HIGH TEMPERATURE THERMOMECHANICAL SURFACE TREATMENT**

## ON RESIDUAL STRESSES IN 9Kh STEEL ROLLS.

The selection of the method for determining residual stresses is confined to a narrow choice because of high hardness and small diameter of specimens. The Sachs method can be used only for a study of the stressed state in solid or hollow thick-walled cylinders with large diameters. The Heine-Bauer method used in this study may be recommended for determining axial residual stresses in thin rods. The distribution and level of residual stresses in 20 mm diameter 9Kh steel work rolls quenched following HF heating and hardening by high temperature thermomechanical surface treatment have been investigated. Residual stresses resulting from quenching in oil are presented for comparison, the contact fatigue limit varies within broad ranges during surface treatment. (Edited author abstract). 4 Refs.

## Stresses

**091959 MEASUREMENT OF ACTUAL STRESS AND TEMPERATURE ON THE ROLL SURFACE IN ROLLING (1ST REPORT, DEVELOPMENT OF A SENSOR FOR DETECTING PRESSURE AND FRICTIONAL STRESS).** A stress sensor for detecting pressure and frictional stress acting on the roll surface in rolling has been developed. Using this sensor, not only pressure but also frictional stress in the rolling direction and frictional stress in the width direction can be detected at the same time. The measuring performance of this sensor is investigated and an example of the measurement in rolling is shown. The accuracy of the measured data is confirmed. (Author abstract) In Japanese. 5 refs.

**Wear** See Also PAPERMAKING MACHINERY—Rolls; ROLLING MILL PRACTICE—Hot Rolling; WEAR OF MATERIALS.

**091960 WEAR AND DETERIORATION OF ROLLING ROLL AND PROCEDURE OF ANTI-WEAR.** Roll wear and surface deterioration generally depend on the rolling load and roll surface temperature at the contact arc. Cast steel and adamite rolls should preferably be used under conditions that will bring the roll surface temperature to 600°C at which there will be formed a strong black scale film on the roll surface. Grain cast iron rolls on which a black scale film hardly develops should be used at surface temperatures around 700°C. So, to minimize temperature rise on the roll surface at the contact arc, it is clarified that reduction of friction coefficient is an excellent expedient. When roll lubricants are used in rolling process, the friction coefficient at the contact arc decreases largely and the anti-wear durability of the roll is strengthened. Roll surface roughening damage is influenced by the thermal fatigue of the surface layer in a hot strip mill. (Edited author abstract) In Japanese. 9 refs.

Ohnuki, Akira (Takasago Tekko Corp, Tokyo, Jpn). *J Jpn Soc Lubr Eng* v 32 n 9 1987 p 621-626.

**091961 SIMULATION OF ROLLER GUIDE WEAR IN A HIGH TEMPERATURE TEST RIG.** Surface studies and the observed linear increase in wear vs. number of tests cycles together with the linear increase in wear rate with normal force clearly show that abrasion by disc oxides is the dominant wear mechanism at elevated temperatures. The influence of disc temperature on the operating wear mechanisms as well as the resulting wear

are also evaluated. A quantitative classification of four guide roller materials, a high chromium tool steel, two grades of high chromium cast iron and a cermet, has also been made. The hard cermet, containing about 50 vol.% titanium carbides, proved to be the outstanding material in roller guide applications. (Edited author abstract) 14 refs.

**091962 DEVELOPMENT OF STRUCTURE AND CONSTRUCTION OF REGRESSION MODEL OF WEAR OF SHEET MILL WORK ROLLS.** On the basis of an investigation on a continuous 2000 hot wide strip mill, a mathematical model describing wear of sheet mill work rolls was developed. Adaptable regression models make it possible to monitor the rolling process reliably and to obtain information on the parameters entering the model directly during roll operation on the mill. Roll wear can be predicted at the stage of development of rolling schedules. (Author abstract). 5 Refs.

Shatalov, R.L. (All-Union Correspondence Polytechnic Inst, USSR); Grigoryan, G.G.; Sharov, A.A.; Savin, V.A. *Steel USSR* v 17 n 9 Sep 1987 p 416-419.

**091963 HARDNESS AND WEAR RESISTANCE OF ADAMITE FOR WORK ROLLS IN HOT ROLLING MILL.** The hardness of adamite roll materials for hot work rolls depends on the amount of hardness of coarse carbides and the hardness of the matrix. The high-hardened adamite roll materials have excellent wear resistance when the amount of coarse carbides is about 8 percent, but resistance deteriorates when the amount exceeds a critical level. As the volume of coarse carbides increases, the spacing between them decreases. The area of coarse carbides in contact with hot strip surfaces also increases to induce a partial disintegration of brittle carbides. The rolls with about 8 percent of coarse carbides have a hardness from Hs 65 to 70. (Edited author abstract). 7 Refs.

**091964 STRUCTURE AND WEAR RESISTANCE OF ADAMITE ROLL MATERIALS FOR HOT WORKING ROLLS.** The adamite roll materials used for hot working rolls are duplex materials with coarse carbides and matrix. It is desirable that the matrix structure consists of optimum volume fraction and distribution of carbides in order to keep high hardness for better wear resistance. It is concluded that the wear resistance of Adamite is based on its microstructure. 2 refs.

**ROOFS** See Also BUILDINGS—Climate Control.

**091965 PERIMETER FLASHING - WILL YOURS HOLD?** Incorporating 'can't strips' or 'gravel stops' the flashing assembly is intended to provide a water-tight seal between the roof edge and building wall. Flashing assemblies are used on roofs that are generally flat or slightly sloped, made up of various components, and surfaced with built-up or single-ply membranes. The flashing assembly consists of heavy sheet metal (generally preformed galvanized iron, cold-rolled copper or aluminum), wood nailers and cant strips. Improper installation or maintenance of these components can lead to failure of the flashing assembly, thus providing a starting point for wind uplift followed by failure of the associated built-up roof components. This article discusses loss history, design and construction considerations, and existing installations.

Anon (Kemper Group, New York, NY, USA). *Build Stand* v 57 n 1 Jan-Feb 1988 p 8-9.

**091966 SNOW LOADS ON SLOPED ROOFS.** The author proposes design recommendations using the results from a field investigation, wherein the effects of slope and thermal environment are measured independently of other snow accumulation factors. Data from instrumented sloped roofs are combined with observations from a group of similar structures. A flat-roof building with four different thermal conditions is monitored as a control for the sloped roofs. Results are widely applicable since the field site has significant snow accumulation during the years of study. Regression analysis is used to formulate new sloped roof coefficient; the coefficient errors are normally distributed. (Edited author abstract) 18 refs.

## Analysis

**091967 SHAPES, SAGS AND TENSIONS OF THE HANGING ROOFS WITH HORIZONTAL BOUNDARIES.** The author derives the equations for surfaces of hanging roofs with horizontal boundaries and formulas for their sags, tensions, horizontal stretches and reactions. The paper contains solutions for the roofs with circular, elliptical, triangular, square, hexagonal and rectangular boundaries. Circular and elliptical roofs with central holes as well as roofs over the sectoral plans and halls bounded by two circular cylinders are also considered. The derived relations and formulas apply to orthotropic membranes and rectangular cable networks with two perpendicular horizontal components of tension forces. The presented solutions are based on Poisson's differential equation. The maximum sag of the hanging roofs with horizontal boundaries occurs in the place with the horizontal tangent plane where the roof is acted on by the horizontal tension components only. The maximum tension which is equal to the maximum resultant reaction acts in the place and direction of the maximum slope which is at the horizontal boundary. (Edited author abstract) 13 refs.

## Cable Suspended

**091968 VARIOUS SHAPES OF CABLES AND CYLINDRICAL SUSPENSION ROOFS WITH COMPLEX VERTICAL LOADS.** The author derives the equations of the cable curves and surfaces of the cylindrical suspension roofs under various kinds of vertical loads. The loads distributed across the horizontal span are expressed by an algebraic series and polynomials as well as by trigonometric sine and cosine series. Accordingly, the algebraic or transcendental cable curves are obtained. The vertical loads distributed along the cable or on the surface of a cylindrical suspension roof are expressed by the algebraic series and polynomials. The corresponding relations represent the coordinates of the cable curve in the parametric form depending on the angle of inclination. The author derives relations for the curves formed by the cables acted on simultaneously by the loads uniformly distributed across the horizontal span and along the cable curve. It is shown how the shape of the cable curve and the surface of a cylindrical suspension roof depend on the kind of loading and that the catenary and parabola are special cases of the derived general relationships. (Edited author abstract) 16 refs.

Sobotka, Zdenek. *Acta Tech CSAV* v 32 n 4 1987 p 479-510.

## Components

**091969 ROOFING: MORE THAN THE SUM OF ITS PARTS.** Selecting a roofing system neither starts nor ends with the membrane. With that in mind, this issue is devoted to some of those other major considerations involved in roofing selection: decks, vapor barriers, insulation, penetrations, perimeters, wind uplift and fire resistance, warranties and guarantees, testing and inspection, and specifications. The intent is to look at the roofing system from a variety of viewpoints and consider components, in addition to the membrane, that play an integral role in a roof's success. What goes under the roof continues to be a primary concern in the selection of roofing membranes. Specific concerns for the type of deck under a particular membrane are best left to the manufacturer of the membrane.

Raeber, John A. *Constr Specifier* v 40 n 11 Nov 1987 p 34-35.

**091970 NUTS AND BOLTS OF PERIPHERAL ROOFING COMPONENTS.** When it comes to roofing for new projects or renovation work, designers and specifiers are primarily concerned with selecting either built-up roofing or single ply membranes. Preoccupied with the selection of these membrane systems, they may inadvertently neglect the peripheral components. Although roofing membranes are critical in accommodating the various criteria for each project, they constitute only one component of the overall roofing system. Careful consideration must be given to selecting individual peripheral components. These peripheral components are required to support, attach, terminate, seal, vent, protect, isolate, drain, accommodate movement, or provide access. 1 ref.

Israel, Sheldon B. (Construction Specifications Inst, Fort Lauderdale, FL, USA). *Constr Specifier* v 40 n 11 Nov 1987 p 44-49.

## Concrete

**091971 DURABILITY OF NATURAL FIBERS IN CEMENT-BASED ROOFING SHEETS.** Natural fibres such as sisal, jute, ramie and coir can be used as reinforcement in cement-based roofing sheets. Natural fibre concrete is a low-cost material. With time the natural fibres decompose producing a brittle composite. Studies reported here shows that this embrittlement can be prevented by replacing a part of the ordinary Portland cement by highly active pozzolanic materials, like silica fume or rice husk ash. (Author abstract) 5 refs.

Gram, H.E. (Swedish Cement & Concrete Research Inst, Sweden); Nimityongskul, P. *J Ferrocem* v 17 n 4 Oct 1987 p 321-327.

**091972 TIPS ON ROOFING CONCRETE ROOF DECKS.** If properly designed and constructed, almost any roofing system will work on a concrete roof deck. But because not all concrete roofs are the same, determining which roofing system will perform best requires the answers to many questions: How long must the roof last? Must it endure constant sun or severe winters? Must it withstand high winds? Is there usually a lot of traffic on the roof? Is the concrete roof deck dead level or sloped? Is it precast or cast in place? A complete roofing system for a low-slope roof consists of a vapor retarder (if required), insulation (if desired), and a roof membrane and flashing system. This paper summarizes numerous combinations of roofing materials and installation methods.

Koziol, Richard (Wiss, Janney, Elstner Associates Inc, Northbrook, IL, USA). *Concr Constr* v 33 n 2 Feb 1988 p 4p.

**091973 PRECAST CONCRETE ROOF STRUCTURE: FAILURE AND REPAIR.** Heavy concrete fragments crashing into the floor of a huge warehouse building, from an overhead precast structure, calls for an investigation to determine the cause of this phenomenon

and stop it. Field observations show that the roof double-tees are bearing on the edge of improperly reinforced concrete flanges of precast I-griders. This causes cracking and eventual fallout of fragments of the girder flange. As a result, bearing of some of the double-tees is reduced to 1.5 in., an unacceptable amount. Such precarious support could cause sudden and catastrophic failure. The shortcomings of the original design are identified, and a correct design that would have prevented failure is presented. Additional aspects of the subject are discussed. (Edited author abstract). 7 Refs.

Gurfinkel, German (Univ of Illinois at Urbana-Champaign, Urbana, IL, USA). *J Perform Constr Facil* v 2 n 3 Aug 1988 p 144-158.

**Concrete Construction** See SKATING RINKS—Structural Design.

**Concrete Shell** See Also AUDITORIUMS—Restoration.

**091974 ADVANTAGES OF PERLITE CONCRETE ROOF DECK SYSTEMS.** Insulating concrete roof deck systems have proven their worth on millions of square feet of major buildings from coast to coast. In the past 15 years the most widely used insulating concrete has been one prepared from perlite aggregate. 'Perlite' is not a brand name but a petrographic term for a naturally occurring, asbestos free, siliceous rock defined in the dictionary as 'volcanic glass with concentric shelly structure'. The feature that distinguishes perlite from other volcanic glasses is that when heated to a suitable temperature it expands, like popcorn, to four to 20 times its original volume. The glassy, closed cellular structure of expanded perlite resists water penetration and results in concrete mixes requiring about 30 percent less water than vermiculite and other open celled aggregates.

Pruter, Walter F. *Constr Specifier* v 40 n 11 Nov 1987 p 52-55.

**Construction** See Also STADIUMS—Roofs.

**091975 AIR FORCE BUILT-UP ROOF TOLERANCES.** The need to control workmanship has been identified as important in obtaining a built-up roof which will perform adequately. The use of tolerances to evaluate workmanship has various degrees of acceptance. If it is determined that variances are to be used in the contract specifications, the designer is faced with a wide range of recommendations. An investigation of past variances from specified quantities does not alleviate the problem. There appear to be no clearly identified allowable variances that a contractor should be able to attain, given current construction and quality assurance procedures; at least not as evidenced by a frequency analysis of variances occurring in Air Force roofing projects. Selecting realistic tolerances is difficult because of the many factors and variables involved in construction. In addition, a built-up roof is a complex system with interacting components.

Lavigne, Dale R. (US Air Force, USA). *Mil Eng* v 79 n 517 Sep-Oct 1987 p 492-495.

**Cooling**

**091976 HEAT TRANSPORT MODEL FOR ROOF MIST SPRAY SYSTEMS.** The Roof Mist Spray System (RMSS) employs evaporative cooling for heat removal. A light water mist is periodically sprayed on the roof of a building during warm days. The water evaporates between applications, causing a cooling of the roof surface. This reduces the temperature gradient between the roof surface and the building interior, thus reducing the load on the building's air conditioning system. According to commercial vendors, such a system can be installed at less than one-fifth of the insulation costs for the same effect. Additionally, the roof life can be doubled due to lower surface temperatures. The purpose of this study was to develop a heat transport model to predict the cooling load on buildings. 6 refs.

White, Charles R.; Hanley, Thomas R.; Mathiasmeier, Kenneth J. *ASHRAE J* v 29 n 10 Oct 1987 p 39-41.

**091977 ROOF SPRAY COOLING SYSTEMS.** Evaporative roof spraying systems are most effective when the plant has a large roof area in proportion to exposed walls and sensible-to-total heat ratios are high. Water consumption seldom average more than 10 oz/100 sq ft of roof surface in a 6-min period, but the roof temperature is typically reduced 40 to 60°. This article discusses the evaporative cooling process, applications, roof protection, and economics.

Abernethy, Dick (Fan-Jet Roof Cooling Systems, Carrollton, TX, USA). *Plant Eng (Barrington Ill)* v 42 n 3 Mar 10 1988 p 178-180.

**Coverings**

**091978 EVALUATION OF THE CRACK-BRIDGING ABILITY OF EXPOSED ROOF COATINGS.** A major problem with single-layer in situ applied or prefabricated roofing membranes, exposed to intensive solar radiation in subtropical climates, is their long-time ability to bridge over working cracks. A performance test, suitable for accelerated testing and evaluation of the crack-bridging ability of roofing membranes, exposed to real climatic conditions and experience gained with its use are described. The testing device consists of a reinforced concrete slab measuring 100 cm x 50 cm x 5 cm on free-moving horizontal supports. A transverse crack of controlled width is induced at mid-length. The membrane under test can be applied before or after inducing the crack. Typical temperature variations, and resulting crack widths recorded during the calibration period, are discussed. Included also are results of comparative tests performed with the device on different roofing materials. (Edited author abstract) 3 refs.

Jaegermann, C. (Technion-Israel Inst of Technology, Haifa, Isr); Puterman, M. *Mater Struct* v 20 n 120 Nov 1987 p 403-407.

**091979 COPING WITH MEMBRANE ROOF PENETRATIONS.** Flashings are more often the point of entry for water than the roof membrane. One study of 163 roofs indicated five times as many flashing leaks as leaks in the roof surface. Guides to flashing usually start with the customary edge flashing and base flashing conditions, which indeed account for the bulk of the material and labor in flashing a typical roof. In flat roofs the base and edge flashings are the outer boundary of the plane we call the roof surface, which is often more like a pan: turned up at the edges. This article concentrates on the interruptions that occur within that plane or pan, broadly called penetrations, whether they are curved holes, joints, or small holes made for pipes and posts.

**Deformation** See GARAGES—Concrete.

**Design** See TANKS—Roofs.

**Drainage**

**091980 DESIGNERS' NOTEBOOK: THE ROOF TOP DRAIN.** In order to provide a receptacle to drain cooling towers, coil drains, etc., located on the building roof, a roof top fixture such as a 'Roofceptor,' floor sink, or open site drain must be installed. The article presents 4 possible fixture designs. The fourth solution suggests that a fixture is not needed but rather an open waste line through roof, or perhaps an adequate or oversized vent for the equipment drain. As long as this open waste line meets all minimum termination requirements of a vent through the roof, it should not only be a safe and sanitary method of receiving an indirect equipment drain but a logical one as well. The proposed solution to this problem would eliminate the added cost of the fixture, the extra roof penetration, and the need for frost protection for the fixture trap.

Smith, Larry E. (Systems Design, Carlsbad, CA, USA). *Plumbing Eng* v 15 n 9 Nov-Dec 1987 p 11-12.

**Failure**

**091981 TESTING SINGLE PLY'S WEATHERABILITY.** Wind, rain, pollution, and other natural elements all contribute to single ply roofing system failures. But without a doubt, the sun's powerful ultraviolet (UV) rays are responsible for causing more damage to single ply roofing systems than any other weather-related element. Destructive UV rays (those in the 290 to 350 nanometer range) are responsible for the failure of thousands of roofs each year. Once these powerful UV rays begin to break down the chemical bonds in the polymer chains that make up many single ply roofing membranes, the other natural elements ultimately finish the job of destroying the integrity of the roofing membrane. Six common tests are widely used to evaluate the long-term weatherability characteristics of single ply roofing materials: real-time testing; enclosed carbon arc testing; sunshine carbon arc testing; xenon arc testing; QUV testing; and EMMAQUA concentrated sunlight testing.

Peterson, Arnold (J.P. Stevens & Co, North Hampton, MA, USA). *Constr Specifier* v 40 n 11 Nov 1987 p 21, 23, 25.

**091982 ROOF COLLAPSE UNDER SNOWDRIFT LOADING AND SNOWDRIFT DESIGN CRITERIA.** This paper summarizes an investigation of the roof collapse that occurred at Waterville Junior High School in Waterville, Maine, on February 9, 1978, after a heavy snowstorm. The primary cause of the collapse is found to be that load from drifting snow was not considered in the design; the physical cause is found to be severe overloading of open web joists. Had the designer followed accepted engineering practice standards for drifting snow existing at the time of design, the collapse would not have occurred. The paper also compares the snowdrifts observed at Waterville Junior High School to accepted engineering practice at the time of design, to other observations of snowdrifts, and to recent code criteria for snow drifts. The proper character of drift loads is found not to have been recognized by the structural engineering profession at the time of the collapse, and presently, the ability of the profession to predict snowdrifts and their loads is limited. Recommendations for improving predictions of snowdrift loads using recent code criteria are presented. (Author abstract) 16 refs.

**Fire Protection** See Also TRUSSES—Fire Resistance.

**091984 BRANDSCHUTZ F 90 FUER TRAPEZBLECHDAECHER.** [F 90 Fire Protection Board for Trapezoidal Sheet Roofs]. Trapezoidal sheeting is being used to an increasing extent for roofs and ceilings. The thinness of such building components necessitates a special method of fire protection. With their Thermax M fire protection board Isovolta can offer a solution which, apart from being highly economical, offers F 90 fire protection. (Author abstract) In German.

Anon (Isovolta, Wiener Neudorf, Austria). *Stahlbau Rundsch* n 68 Apr 1987 p 9.

**Fire Resistance**

**091985 WIND UPLIFT ON ROOFS.** This article represents a perspective on wind uplift as it pertains to roof systems. It will attempt to review the relationship of wind uplift to fire, describe the Underwriters Laboratories, Inc., (UL) and Factory Mutual Research Corporation (FMRC)

tests, and recommend the best design for a built-up roof (BUR) or single ply roof system today. Is there a relationship between wind uplift and the fire resistance of a roof system? From the author's viewpoint, there is. This risk comes not from external fire sources - where, for instance, burning brands are blown onto a roof deck - but from internal fire sources.

Hoover, Stephen R. *Constr Specifier* v 40 n 11 Nov 1987 p 76-79.

## Fires

**091986 ROOFS AND FIRE.** Roof constructions have to satisfy a number of structural fire protection requirements which take into account the following: possible ignition and extensive flame spread over the external surface caused by heat radiated by a fire in an adjacent building (or another part of the same building) and by flying burning brands; and the risk that once a roof had been ignited on the outside the fire will penetrate to the inside of the building; the need, in some circumstances, to prevent a fire inside a building spreading to a nearby building or an upper part of the same building; and the possible effects of the roof on the fire spread within the building. The author describes how roofs are tested and examines some case studies. Fire experience suggests that there are shortcomings in current legislation. 13 refs.

Day, Terry. *Fire Prev* n 201 Jul-Aug 1987 p 18-23.

## Insulation

**091987 BEWERTUNG DES DIFFUSIONSVERHALTENS BEI DER ZUSATZDAEMMUNG VON WARMDAECHERN.** [Evaluation of the Diffusion Behavior in Additional Insulation of Thermally Insulated Roofs]. In order to improve the energy conservation quality of insulated roofs in existing single-floor industrial buildings, it is possible to add additional insulation. In the case of 80 mm thick mineral wool, laminated strips under a new roof skin, there arise normally no problems. In the case of relative inferior air moisture levels of 65%, two condensation planes arise in additionally insulated roofs, which is not permissible. The possibilities of avoiding the condensation plane by means of perforation of the old roof skin or overdimensioning of the additional insulation are investigated. Perforation is not an appropriate solution. Overdimensioning leads to a permissible solution from the diffusion technical point of view, but requires excessive use of the insulating material. In German. 1 ref.

Schwarz, Frieder (Bauakademie der DDR, East Ger). *Bauplanung Bautech* v 41 n 2 Feb 1987 p 54-55.

**091988 UEBER DIE LUFTDURCHLAESSIGKEIT GENEIGTER DAECHER.** [Air Tightness of Sloped Roofs]. The effects of different types of material for roofing on the heat losses and condensation of ceilings have been studied by measurements. **091989 WETTING OF POLYSTYRENE AND URETHANE ROOF INSULATIONS IN THE LABORATORY AND ON A PROTECTED MEMBRANE ROOF.** When subjected to a sustained temperature gradient in the presence of moisture in laboratory wetting tests, urethane and expanded polystyrene roof insulations accumulate enough moisture to significantly reduce their insulating ability. Extruded polystyrene is quite resistant to moisture in such tests. But the vapor drive is not as great in actual roofs and it may reverse direction, thereby seasonally drying the insulation. To determine how well the laboratory tests could predict the wetting rate of insulation in actual protected membrane roofs, extruded and expanded polystyrene and urethane insulations were installed in a protected membrane roof in Hanover, NH. (Edited author abstract) 13 refs.

Tobiasson, Wayne (US Army Corp of Engineers, Hanover, NH, USA); Greatorex, Alan; Van Pelt, Doris. *J Therm Insul* v 11 Oct 1987 p 108-119.

**091990 VERMICULITE ROOF INSULATION SYSTEMS.** Vermiculite concrete offers fire protection for the roof system because it is non-combustible. In addition, it can easily be sloped to drain water, has a monolithic surface, and bonds securely to the structural substrate, providing a high degree of wind-uplift resistance. Polystyrene continues to be the most cost effective insulation that is both dimensionally stable and minimally affected by moisture. The inclusion of polystyrene board in vermiculite roof insulation allows the system to provide more than 34" R insulation.

Dudley, Hubert T. (W.F. Grace & Co, Cambridge, MA, USA). *Constr Specifier* v 40 n 11 Nov 1987 p 62-65.

**091991 FOAMED PLASTIC ROOF INSULATION.** Foamed plastic insulation is widely used in the commercial low-slope roofing market, with total 1986 use estimated at 2.3 billion board feet. A variety of types are available, each having different properties and benefits. Some considerations include compatibility with other roofing system components, type of substrate, fire performance of the overall system, in-service durability of the product, needs for creating slope, method of attachment, resistance to moisture (e.g., internal moisture drive/condensation, moisture in event of leak, or moisture when placed above membrane in PMR applications), and long term R-value retention. This article summarizes the differences between the four basic generic types of rigid foam plastic insulation: extruded expanded polystyrene (XEPS), molded bead polystyrene (MEPS), polyurethane/polyisocyanurate (PUR/PIR), and phenolic.

Petersen, Wayne (Dow Chemical Co, Midland, MI, USA). *Constr Specifier* v 40 n 11 Nov 1987 p 66-69, 71, 73-74.

**091992 VENTS AND VAPOR RETARDERS FOR ROOFS.** Vents and vapor retarders are features incorporated into roofing systems to prevent moisture from condensing within the roof. Their need in building envelopes depends on the local climate, the temperature and moisture conditions within the building, and the type of materials and systems used for the envelope. Condensation problems in roofs are usually caused by moisture in indoor air that moves upward into the roofing system in cold weather. However, problems can also occur in hot, humid regions when moisture in outdoor air condenses within a roof, particularly above air-conditioned spaces. This article is primarily concerned with condensation in cold weather, but the warm weather problem will also be addressed. 22 refs.

Tobiasson, Wayne (US Army Corp of Engineers, Hanover, NH, USA). *Constr Specifier* v 40 n 11 Nov 1987 p 80-84, 87-88, 90.

## Maintenance

**091993 WHEN IS IT SAFE TO RE-COVER AN EXISTING ROOF?** The reason roof replacement is under consideration is because the existing system leaks. Almost never is a roof considered for major work simply because it has exceeded its projected life span. More likely, it has leaked and been patched on many occasions over a long period of time. This means that water has entered the existing system and is probably being retained in the insulation. Unless the existing roof is removed, there is virtually no way of knowing the condition of the deck underneath it. Simply looking at the deck from below may not uncover the hazards - decks deteriorate from water coming in from above, not below.

Warseck, Karen (Hoffmann Architects, Atlanta, GA, USA). *Natl Eng* v 92 n 3 Mar 1988 p 8-9.

## Materials

**091994 EXPLORING THE OPTIONS: SINGLE PLY ROOFING.** Today, single ply is an accepted alternative to built-up roofing (BUR) and is no longer

marketed primarily as a reroofing product to be used over intact BUR. It may be installed loose laid and ballasted, or it may be fully adhered, partly adhered, or mechanically fastened. The single ply system does not vary a great deal from the BUR system in that they both use a structural deck, vapor retarder, and insulation, or a form topped by a poured-in-place insulating fill as a substrate. The difference is in the single ply membrane: a single sheet of rubber, plastic, or modified bitumen taking the place of three or four plies of tar- or asphalt-saturated felt laminated with asphalt or coal tar pitch. This article discusses single-ply roofing materials, applications, installation procedures, and other aspects of the subject.

Hoover, Stephen R. *Constr Specifier* v 40 n 12 Dec 1987 p 92-100, 102-103.

**091995 ROOFING: COATED COIL'S NEXT GROWTH MARKET?** Roofing may challenge food cans as the next big growth market for coil coated steel. Construction is already steel's third largest market. There are two main roofing targets for the coil coating industry to aim at: the nonresidential, low-slope market, which is principally commercial and light industrial construction, and the residential market.

Church, Fred L. (Modern Metals, Chicago, IL, USA). *Mod Met* v 43 n 11 Dec 1987 5p between p 28 and 36.

**091996 STUDY OF SOME VARIABLES AFFECTING THE PROPERTIES OF SULFUR-REINFORCED SUGARCANE RESIDUE-BASED BOARDS.** Low density boards made with sugar-cane residue (bagasse) fiber, were later post-treated with either sulfur or sulfur modified with Escopol (a drying type of oil). Beating time, pre-treatment (addition of phenolic resin or wax to slurry before board formation) and post-treatment were the manufacturing variables employed in the study. The effects of the variables on the physical and mechanical properties (dry and after 48 h water soaking) of the products were investigated, using analysis of variance technique and basing significance on 10%, 5% and 1% probability levels. Although the boards were affected by all the variables, the deterministic factor was the amount of sulfur or sulfur/Escopol picked-up during post-treatment. (Edited author abstract) 8 refs.

Nnabuife, Elias L.C. (Anambra State Univ of Technology, Awka, Nigeria). *Indian J Technol* v 25 n 8 Aug 1987 p 363-367.

**091997 PROCESS TECHNOLOGY OF CERAMIC ROOFING TILES FROM RED IRAQI CLAY.** A study on the utilization of red Iraqi clay for the production of ceramic tiles, to be used as protective wearing cover for flat roofs, has been carried out. Local quartz sands have been added in varying proportions to the clay to overcome the drying and firing cracks. The optimal laboratory results were adapted on pilot scale. The characteristics of the manufactured tiles were compared with those of the concrete tiles currently used in Iraq. (Edited author abstract) 8 refs.

Girgis, Lamey G. (Nat'l Research Cent, Cairo, Egypt); El-Rawi, S. *Sprechsaal* v 121 n 1 1988 p 56-61.

**091998 GRANULE EMBEDMENT ON SHINGLES AND ROOFING MEMBRANES.** Samples of shingles and modified bituminous membranes covered with stone, slag or slate granules were tested for the amount of granules applied and the coverage provided to the bitumen. The granule embedment in the as-received condition and after wetting was measured by scrubbing the samples with 50 strokes of a steel wire brush. Five representative samples out of the thirteen were also subjected to an extended scrub test, where the number of scrub strokes was increased to 150 (in intervals) to evaluate the retention. The results showed significant variations between samples. The requirement of a fixed amount of granule loss exists in most standards. Although this is adequate for quality control, the loss should be proportional to the quantity of granules applied, rather than a

fixed amount. Proper assessment of granule adhesion requires testing for wet granule loss, for the initial granule coverage and for the tendency for granules to detach under extended scrubbing. (Author abstract) 5 refs.

**Plastics Applications** See Also ELASTOMERS—Applications; POLYVINYL CHLORIDE—Applications.

**091999 NEW LABORATORY PROCEDURES TO EVALUATE THE DURABILITY OF ROOFING MEMBRANES.** Demand continues to increase rapidly for a method to test the durability of new generation roofing membranes. New generation membranes mean thermoplastic, thermoset and modified bituminous membranes. Current laboratory procedures used to evaluate the durability of roofing membranes use artificial weathering devices which attempt to simulate the primary weathering agents. Although this is probably a valid method for evaluating a specific product, a problem arises when one wants to evaluate several different types of roofing materials in the same test. In this article the author describes the features and advantages of using thermal analysis or thermo-analytical techniques to bridge the gap between test procedures for different polymeric membranes.

Farling, Michael S. (Carlisle SynTec Systems). *Rubber World* v 197 n 4 Jan 1988 p 20-23, 48.

## Protective Coatings

**092000 COATINGS FOR ROOFS AND DECKS DON'T HAVE TO BE UGLY.** Several types of coating systems for roofs and decks are described. Special high-strength polyurethane solvent-based coatings, one- and two-component systems, have performed excellently as topcoats. Single-component, moisture-curing polyurethanes which are fluid-applied and provide multi-layered, monolithic-textured waterproof toppings for both plywood and concrete substrates are easy to apply, economical and functional. Epoxy has good properties as a base coat in many applications on concrete and metal. In polyurethane-hypalon coating systems, the polyurethane provides the usual excellent physical properties and ease of application, while the hypalon topcoat ensures maximum weatherability. Butyl as a topcoat is of definite interest because of its low price and outstanding weatherability. 5 Refs.

Gamero, Robert. *Elastomerics* v 120 n 9 Sep 1988 p 28-29.

## Repair

**092001 MEMBRANE AND FLASHING CONDITION INDEXES FOR BUILT-UP ROOFS, VOLUME II: INSPECTION AND DISTRESS MANUAL.** As part of the system for built-up roofs, this volume presents the standardized information needed to conduct the visual inspection survey, including names, descriptions, severity levels, measurement criteria, causes and photographs of membrane and flashing distresses. Procedures for distress density calculations are also provided. Roof inspectors can use this information to objectively determine the indexes that reflect the (1) ability of the membrane and flashing to perform their functions, (2) needed level of maintenance, and (3) waterproof integrity. (Edited author abstract)

Shahin, Mohamed Y. (US Army Construction Engr Research Lab, Champaign, IL, USA); Bailey, David M.; Brotherson, Donald E. *Tech Rep US Army Corps Eng Constr Eng Res Lab* M-87/13 v 1-2 Sep 1987 98p.

**092002 MEMBRANE AND FLASHING CONDITION INDEXES FOR BUILT-UP ROOFS, VOLUME I: DEVELOPMENT OF THE PROCEDURE (UNCLASSIFIED).** Because no systematic procedure exists to determine priorities and select repair strategies for low-slope roofs, the U.S. Army Construction Engineering Research Laboratory (USA-CERL) is developing a roof

maintenance management system that will provide a practical decisionmaking procedure to identify cost-effective repairs. This volume describes part of the overall system; the development and verification of roof condition indexes for rating built-up roofs, based on a visual distress survey. Separate indexes were developed for the membrane and flashing components. Each index is expressed as a numerical rating ranging from 0 to 100, and provides a measure of the component's ability to perform its function, needed level of maintenance, and leak potential. The roof condition indexes have been field tested and validated through the assistance of several roof experts from both the military and private sectors. (Edited author abstract)

Shahin, Mohamed Y. (US Army Construction Engr Research Lab, Champaign, IL, USA); Bailey, David M.; Brotherson, Donald E. *Tech Rep US Army Corps Eng Constr Eng Res Lab* M-87/13 v 1-2 Sep 1987 33p.

## Service Life

**092003 NONDESTRUCTIVE METHODS FOR INSPECTING SINGLE PLY ROOFING MEMBRANE SEAMS.** Durable, single ply roofing membranes are characterized, among other factors, as having seams that remain watertight over the intended service life of the roofing. Failure of a seam can result in water penetration of the roofing system causing damage to itself, other building components, and building contents, and also loss of thermal efficiency of the roof insulation. Two nondestructive evaluation methods show promise for detecting voids and delaminations in adhesive-bonded, single ply membrane seams. 12 refs.

Rossiter, Walter J. Jr. (Cent for Building Technology, USA). *Constr Specifier* v 40 n 11 Nov 1987 p 92-96, 98, 100.

## Standards

**092004 SPECIFYING MEMBRANE ROOFING. A SYSTEMATIC APPROACH.** Today, writing roofing specifications is complex. First, there are bewildering numbers of membranes and insulations. The latest NRCA Roofing Materials Guide lists over 475 roofing systems and 200 insulations currently marketed in the United States. The specifier must decide how to install the system - by hot hopping, self-adhering, adhering with cold adhesive, torching, mechanically fastening, welding with solvents, welding with heat, or by loose laying and ballasting. He must contend with compatibility of materials, complicated flashing systems, and shorter term guarantees, as well as Underwriters' Laboratories' and Factory Mutual's requirements for fire and wind uplift. This article is arranged in accordance with the CSI Standard Three-Part Section Format. It is desirable to limit the types of membranes on a single project to simplify future maintenance.

Henshell, Justin. *Constr Specifier* v 40 n 11 Nov 1987 p 102-108.

**Steel** See Also STADIUMS—Roofs; STADIUMS—Vienna, Austria.

**092005 DACHAUFBAUTEN IN STAHL.** [Steel Roofings]. For roof storey construction, as necessary when renovating old apartment houses, steel has proved the best solution. The reasons are: slender and thus lightweight sections, easy handling in cramped space, and short construction times. (Author abstract) In German.

Pelikan, E. *Stahlbau Rundsch* n 70 Apr 1988 p 14-15.

## Stresses

**092006 STRESSES IN SIMPLY SUPPORTED FOUR-PITCH SQUARE ROOF.** This paper is an extension of the paper entitled 'Internal Stresses of Combined H.P. Shells'. In this paper, the equation of surface of a Four-Pitch Square Roof is developed. By using the method presented, the stress formulas in the Four-Pitch Square Roof are obtained based on elastic shell

theory. An example is calculated by microcomputer for illustration. (Edited author abstract) 2 refs. In Chinese.

**Structural Analysis** See Also DOMES AND SHELLS—Structural Analysis; SILOS—Wind Effects; STRUCTURAL FRAMES—Steel.

**092007 SHAPES, SAGS AND TENSIONS OF THE HANGING ROOFS WITH HORIZONTAL BOUNDARIES.** The author derives the equations for surfaces of the hanging roofs with horizontal boundaries and formulae for their sags, tensions, horizontal stretches and reactions. The paper contains the solutions for the roofs with the circular, elliptical, triangular, square, hexagonal and rectangular boundaries, the circular and elliptical roofs with central holes as well as for the roofs over the sectoral plans and halls bounded by two circular cylinders. The derived relations and formulae apply for the orthotropic membranes and rectangular cable networks with two perpendicular horizontal components of tension forces. The presented solutions are based on the Poisson's differential equation. The maximum sag of the hanging roofs with horizontal boundaries occurs in the place with the horizontal tangent plane where the roof is acted on by the horizontal tension components only. The maximum tension which is equal to the maximum resultant reaction acts in the place and direction of the maximum slope which is at the horizontal boundary. (Author abstract). 13 Refs.

## Testing

**092010 FURTHER INVESTIGATION OF THE EFFECT OF APPLICATION PARAMETERS ON ADHESIVE-BONDED SEAMS OF SINGLE-PLY ROOF MEMBRANES.** A laboratory study was conducted to determine if a T-peel test was sensitive to differences in initial (7 days) bond strength for adhesive-bonded seams of EPDM (ethylene propylene diene terpolymer) rubber membranes made under different application conditions. The main categories of application parameters investigated were: surface condition (cleanness, moisture) of the rubber; pressure applied; temperature during seam formation; open time. The T-peel test was found to be sensitive to changes in bond resulting from variation of some of the application parameters. Seams prepared using uncleaned

sheets (without removing the talc or other contaminants from their surfaces), or using long open times, had lower average peel strengths than those of the control specimens. Light pressure or high temperature during bond formation produced seams with average peel strengths higher than those of the controls. (Edited author abstract). 17 Refs.

Rossiter, Walter J. Jr. (NBS, Gaithersburg, MD, USA). *Mater Struct* v 21 n 124 Jul 1988 p 243-249.

## Thermal Effects

**092011 ROOF TEMPERATURE VARIATIONS AND THEIR EFFECTS ON ROOF NOISE.** This paper predicts the temperature variations of metal roofs and discusses their implications on thermally induced roof noise. The noise burst characteristics generated by both fast and slow temperature variations are studied for various commonly used roof profiles. Remedial actions aimed at reducing or eliminating thermally induced noise on roofs are suggested. (Author abstract) 14 refs.

## Thermal Insulation

**092012 SEASONAL VARIATIONS IN THE MODES OF HEAT TRANSFER IN A MOIST POROUS THERMAL INSULATION IN A FLAT ROOF.** Glass fiber insulation specimens 60 mm thick, with moisture contents ranging up to 15% by volume, were placed on the roof of the Outdoor Test Building of the Institute for Research in Construction, National Research Council of Canada in Saskatoon, Saskatchewan. The specimens were sealed in polyethylene to prevent the loss of moisture. Thermal conductances were calculated using transfer functions. The results showed an increase in thermal conductance when the weather was warm enough to produce daily reversals in temperature gradient across the wet specimens. In winter, the moisture was deposited in the upper, colder part of the insulation. It was apparently distributed through the upper part of the insulation and not deposited as a solid layer at the top surface, since its effect on thermal conductance indicated by the interior temperature gradient, extended well down in the insulation. (Edited author abstract) 8 refs.

Hedlin, C.P. (Nat'l Research Council of Canada, Saskatoon, Sask, Can). *J Therm Insul* v 11 Jul 1987 p 54-66.

## Wind Effects

**092013 WIND RESISTANCE TESTING FOR ROOF ASSEMBLIES.** Testing standards have been established for rating roofsystem wind resistances. Tests performed by Underwriters' Laboratories (UL) and Factory Mutual (FM) result in product labeling and classifications that affect every roof system installation. Manufacturers wishing to display the UL or FM marking on their products must first submit product samples to the organization for testing and evaluation. Upon satisfactory completion of the test or tests, the manufacturer is given permission to print the appropriate label on its products, provided the material being labeled is the same material as that originally tested by the organization. This article discusses the standards of both organizations.

## Wood See ARCHES—Wood.

## Wooden Construction

**092014 FIRE-RESISTANT COATINGS FOR ROOF/CEILING DECK TIMBERS.** Laboratory tests demonstrated that the intumescent resulting from application of some proprietary flame-retardant paint and coating systems to timber planks could reduce char formation in the planks by as much as 70% during the first 30 min of exposure to ASTM E119 fire conditions. Application of these coating systems to the exposed

surfaces of plank used in construction of heavy timber building assemblies should increase the fire resistance of these components by at least 30 min. This would represent a significant increase in the fire resistance of heavy timber roof systems and could extend the use of this type of construction system to many of the non-residential buildings for which building code authorities presently require fire resistance ratings greater than 1 h. (Author abstract) 9 refs.

## Testing

**092016 DESIGN OF HALL-EFFECT SENSORS FOR MAGNETIC TESTING OF STEEL ROPES.** The design and operating principles of four new Hall-effect sensors for magnetic testing of steel ropes are presented. The radial or tangential component of the magnetic leakage flux can be measured efficiently depending on the shape of the concentrators (rings or sleeves). The output signal can be modified by using multiple constructions of the basic sensors. Different sensors can be used depending on the predominant character of the wear of the rope. (Author abstract) 10 refs.

**092017 ANALYSIS OF DYNAMIC BEHAVIOR OF ROTORS WITH NONLINEAR ELASTODAMPER SUPPORTS. II.** We present the results of analysis of a three-disc rotor with two nonlinear hydrodynamic dampers. The results are compared with the experimental data. We evaluate the accuracy of the modal analysis method and also compare various methods of numerical integration of the equations of motion. (Author abstract) 3 refs.

Borzdzyko, E.V.; Leont'ev, M.K.; Zvonarev, S.L. *Sov Aeronaut* v 30 n 4 1987 p 7-11.

**092018 COMPUTER SIMULATION AND PARAMETER ESTIMATION OF UNCAVITATED SQUEEZE-FILM BEARINGS.** Development of analytical expressions for the oil-film forces of an uncavitated squeeze-film bearing and linearization of these forces are discussed. The linearization provides theoretical expressions for the damping coefficients. An alternative approach is adapted to obtain optimum coefficient values by using a least square estimator together with the oil-film forces generated by a non-linear simulation program. Comparison of the theoretical and optimum values highlights the need to identify the parameters from experimental data. A simple frequency domain estimation method, which requires the measurement of displacements only, is adopted to identify the bearing parameters from simulated out-of-balance response. (Edited author abstract). 10

## Acoustic Emission Testing

**092019 RECHERCHE D'UNE METHODE DE DETECTION PRECOCE DE FISSURATION DE ROTOR PAR EMISSION ACOUSTIQUE.** [Development of an Incipient Rotor Crack Detection Method by Acoustic Emission Technique.]. The objective of the program presented is to develop a method of detection and monitoring of crack growth in machine rotor by application of acoustic emission techniques. This program is performed by R and D Division of Electricite de France, jointly with INSA de Lyon. The first task of the program is relative to the characterization of acoustic emission during a progressive tensile test performed on a NCT specimen. The second task of the program deals with the experimentation of acoustic emission techniques for the monitoring of a specimen during cycling bending tests. The last task of the program is relative to evaluation of application of acoustic emission techniques for a small rotor integrity monitoring during fatigue rotation tests. (Author abstract). 9 Refs. In French.

## Aerodynamics

**092020 FLOW VISUALIZATION AND ANALYSIS OF AERODYNAMICALLY DETUNED SUPERSONIC ROTORS.** The effect of aerodynamic detuning on the supersonic steady and unsteady blade passage flow field is experimentally investigated on a free surface water table by means of color Schlieren and shadowgraph flow visualization techniques. Two aerodynamic detuning mechanisms are considered: (1) alternate circumferential spacing of adjacent airfoils; (2) the replacement of alternate airfoils with splitters. The steady flow visualization demonstrates the significant effect of aerodynamic detuning on the passage flow field and, in particular, the shock wave-airfoil surface intersection locations. The unsteady flow visualization studies show the importance of the interblade phase angle. A mathematical model is also described and utilized to demonstrate the enhanced aeroelastic stability associated with the altered cascade passage shock wave structure due to these aerodynamic detuning mechanisms. (Author abstract) 8 refs.

**092021 AERODYNAMIC INDICIAL RESPONSE AND STABILITY DERIVATIVES OF A ROTOR ANNULUS.** The key to finding the aerodynamic forces acting on a rotor in arbitrary rigid-body motion is its response to indicial input of its individual degrees of freedom. A theory is developed to find such indicial responses for an unloaded rotor annulus moving in its own plane. New rational approximations in the complex-frequency domain are used to find the corresponding transient cascade forces for incompressible flow. The indicial response consists of an initial impulse and an oscillatory decaying part for force components parallel and perpendicular to the applied motion. The harmonic response is also found and is expressed in terms of complex 'rotor-stability-derivatives,' which are essentially the direct- and cross-coupled frequency dependent damping or stiffness force coefficients. Both responses are obtained explicitly in terms of the unsteady cascade characteristics and reduced frequency or time. Parametric studies indicate lowered damping, aerodynamic spring-softening and cross-stiffness whirling forces depen-

dent on the upstream dynamic pressure for perturbation frequencies near the rotor speed. (Author abstract) Refs.

## Analysis

**092022 WHIRLING OF UNSYMMETRICAL ROTORS: A FINITE ELEMENT APPROACH BASED ON COMPLEX CO-ORDINATES.** The equations of motion for the study of the flexural dynamic behavior of a general rotating system, based on the finite method and on the use of complex coordinates, are described. The model can take into account the presence of the nonrotating parts of the machine and can include damping, both of 'viscous' and 'hysteretic' type. If either the rotor or the non-rotating parts of the machine possess axial symmetry, the whirl-spin map of the system and the response to any given unbalance distribution or fixed force system can be directly obtained. In the more general case of an unsymmetric rotor running on an unsymmetric supporting structure, a series solution is sought for the equation of motion. An example shows that a good precision is obtained when using only the first few terms of this series. (Edited author abstract). 26 Refs.

**092023 ON DYNAMIC BOUNDARY CONDITIONS IN THE METHOD OF COMPONENT MODE SYNTHESIS.** To the author's knowledge, no research paper has been published on the dynamic boundary conditions of the CMS (Component Mode Synthesis) method in the nonlinear rotor system. In this paper, the dynamic boundary conditions are considered. According to Routh's equation with non-holonomic constraints, the equations of motions for the nonlinear rotor-bearing systems are derived by CMS method, satisfying all the geometric and dynamic boundary conditions. If the dynamic boundary condition contains derivative terms, the condition will have a significant influence on the behaviour of the solution. If the dynamic boundary condition does not contain derivative terms, the effect of the condition on the behaviour of the solution may seem weak. The condition in this case, however, may be used to reduce the degree-of-freedom of the system. (Edited author abstract). 6 Refs. In Chinese.

**092024 APPROXIMATE METHOD FOR SOLVING THE OFFSET SYNCHRONOUS RESPONSES OF FLEXIBLE ROTOR-SQUEEZE FILM DAMPER BEARING SYSTEM.** In order to simplify the response analyses of flexible rotor-uncentrally SFDB (Squeeze Film Damper Bearing) system, the Equivalent Linearizing Method is used for solving the offset synchronous response of the system; the nonlinear fluid film forces are linearized with offset synchronous response and a set of nonlinear algebraic equations for solving the offset response is obtained. In this set of equations, the motion of rotor disk can be represented by the motion of bearing journal, so that the system's degrees of freedom are decreased. Besides, as the problem of solving differential equations is replaced by solving algebraic equations, the computing time can be saved obviously and the analyses are simplified. Numerical results show that the equivalent solution is very near the real solution in the first harmonic approximation, and that the equivalent linearizing method can save computing time greatly compared with direct integrating method. (Edited author abstract). 10 Refs. In Chinese.

**092026 INFLUENCE OF GYROSCOPIC EFFECT ON RESONANCE AVOIDANCE DURING ACCELERATION OF UNBALANCED FLEXIBLE ROTORS.** Vibration of machines with rotors in critical speed zone has been recently extensively studied. Previous papers have dealt with passage of a rotor through the resonance zone disregarding the gyroscopic effect of the rotor. The condition of a safe passage of the resonance zone for the rotor system without damping is derived. The condition for a safe passage through the zone of critical rotational frequency by a flexible Laval shaft is obtained as a function of magnitude of external damping, critical rotational frequency, disbalance, and mass/inertia parameters. In this paper conditions of rotor safe passage through the resonance are analyzed as a function of zone magnitude of external damping; anisotropy of elastic supports; mass and inertia of the rotor; magnitude of disbalance. Also, a formula is derived to determine maximum vibration amplitude in the resonance zone for a given magnitude of the constant torque of the drive motor; and it is shown, that for large external damping the rotor motion can be considered as quasi steady for study of the rotor passage through the resonance zone. i.e., rotation frequency variation can be neglected. 13 refs.

**092028 UCA BALANCING DEMONSTRATED ON GAS TURBINE ROTOR.** The Unified Constrained Approach (UCA), a tool for the high-speed balancing of flexible rotors, has long been a subject of research of MTI. The value of this technique was recently demonstrated on a gas turbine rotor. During testing, it has been found that large orbits at the dampers tend to cause heating of the damper oil, changing damper performance and consequently the behavior of the rotor. This test illustrates the viability of the UCA in tailoring a balancing approach to the unique requirements of an individual rotor-bearing system. It demonstrates that it is possible to satisfy the criteria necessary for orbit control on this rotor system.

**092029 POSITION ERROR OCCURRENCE IN SELF BALANCERS USED ON RIGID ROTORS OF ROTATING MACHINERY.** A self-balancing method is presented which utilizes freely moving balancing bodies rotating in unison with a rotor to be balanced. Because of resistance to motion, eccentricity of race over which the balancing bodies are moving and the influence of external vibrations, it is impossible to attain a complete balance. Each one of these three factors has been analyzed and its influence on the magnitude of balancing body position errors determined. As a result of some inaccuracy in positioning the balancing bodies, certain residual unbalance always remains. (Author abstract) 9 refs.

**092033 BALANCING DOUBLE-OVERHUNG ROTORS IN THREE CORRECTION PLANES.** Double-overhung rotors, where the main mass is not between the bearings, are now widely used. These rotors are traditionally balanced in two correction planes in the vicinity of the bearings. With overhung rotors, and especially double-overhung rotors, the elastic deflection is affected by the imbalance of the rotor section between the bearings to a greater extent than in the case of end-bearing rotors. Because the initial imbalance is equal to the imbalance to be eliminated, the elastic deflection of the shaft will be proportional to double the initial unbalanced mass between the bearings.

Bulychev, N.Ya. *Sov Eng Res* v 7 n 6 Jun 1987 p 27-28.

**092034 COMPLEX MODAL BALANCING OF FLEXIBLE ROTORS INCLUDING RESIDUAL BOW.** A balancing procedure utilizing the Complex Modal Method is presented for linear flexible rotor dynamic systems including the effect of residual shaft bow. The method does not require trial runs; however, a valid mathematical model of the system dynamics is required to obtain the system's modal parameters, which are used to relate the balance corrections to measured responses. Several balancing strategies based on the extension of previous work are suggested for single-speed

balancing. Two applications are presented: 1) a gas turbine system with computer-generated response data, and 2) an operating steam turbine-generator system. (Author abstract). 9 Refs.

**092036 STUDY OF THE DYNAMIC BEHAVIOR OF ROTOR-BEARING SYSTEMS BY THE FINITE ELEMENT METHOD.** The study of the problems given in this paper is of practical importance in the design of turbomachinery today. Natural characteristics of the rotor-bearing systems were investigated. On the basis of Jeffcott's flexible rotor theory and the finite element method, equations of motion for the rotor-bearing systems with respect to either the fixed frame or the rotary frame were present. Illustration included a single, uniform rotor with bearing supports, a stepped rotor with bearings and rigid disks, and a dual rotor system. Numerical results contained with the whirl modes and whirl speeds. Physical meanings concerning the dynamic behavior of the rotor-bearing systems were detailedly discussed in which the critical speeds related to the excitations were introduced. The computational procedures and results shown in this paper are significant for the understanding of the dynamic behavior of the rotor-bearing systems and helpful for the design of a turbine engine. **092037 TRANSIENT DYNAMIC ANALYSIS OF ROTORS USING THE COMBINED METHODOLOGIES OF FINITE ELEMENTS AND TRANSFER MATRIX.** A new approach is proposed to predict the dynamic behavior of rotor-bearing systems in time domain using the combined methodologies of finite elements and transfer matrices. This approach makes use of the finite element method to model symmetric shafts and then transforms the system properties to transfer matrix mode. The formulation provides flexibility to include both linear and nonlinear system models, often encountered in rotor dynamic applications. Few example rotor cases had been studied and the results were compared with those obtained using finite element method. This establishes that considerable savings in computational effort can be achieved without losing any accuracy. (Author abstract). 16 Refs.

**092038 INSTABILITY AND UNBALANCE RESPONSE OF DISSYMMETRIC ROTOR-BEARING SYSTEMS.** The study deals with the instability and unbalance response of dissymmetric rotors, when periodic differential equations are impossible to avoid. The method which yields motion instability is based on an extension of

the well-known Floquet theory. A transfer matrix over one period of the motion is obtained, and the stability of the system can be tested with the eigenvalues of the matrix. To find the instability and the unbalance response, the Newmark formulation is used. Here, the dissymmetry comes either from the rotor or from the bearings in such a way that it is possible to solve a regular differential system without periodic coefficients, either in the stationary coordinate system or in the rotating one. (Edited author abstract). 18 Refs.

## Computer Aided Design

**092040 APPLICATION OF ADVANCED COMPUTATIONAL CODES IN THE DESIGN OF AN EXPERIMENT FOR A SUPERSONIC THROUGH-FLOW FAN ROTOR.** Increased emphasis on sustained supersonic or hypersonic cruise has revived interest in the supersonic throughflow fan as a possible component in advanced propulsion systems. Use of a fan that can operate with a supersonic inlet axial Mach number is attractive from the standpoint of reducing the inlet losses incurred in diffusing the flow from a supersonic flight Mach number to a subsonic one at the fan face. The data base for components of this type is practically nonexistent; therefore, in order to furnish the required information for assessment of this type fan, a program has been initiated at the NASA Lewis Research Center to design, build, and test a fan rotor that operates with supersonic axial velocities from inlet to exit. This paper describes the design of the experiment using advanced computational codes to calculate the unique components required. (Edited author abstract) 24 refs.

## Electromagnetic Field Effects

**092043 ELECTROMAGNETIC CONTROL OF OIL-FILM SUPPORTED ROTORS USING SPARSE MEASUREMENTS.** An electromagnetic controller is applied to a flexible rotor supported by two oil-film bearings. The synchronous vibration is controlled by using a combined estimation and optimization algorithm. This requires no a priori knowledge of the system model. The effect of using a limited number of measurement sites on the controller performance is assessed. Optimum measurement sites are defined. The results of both computer simulations and experimental studies are presented. It is shown that the strategy developed by the authors can reduce the synchronous vibration to less than 10 percent of the uncontrolled response. The open-loop adaptive strategy can be applied to reduce the time required for in-situ tuning of magnetic controllers. (Author abstract). 12 Refs.

**092044 INFLUENCE OF RELATIVE SLIP RANGE AND CONTACT MATERIAL ON THE FRETTING FATIGUE PROPERTIES OF 3.5NiCrMoV ROTOR STEEL.** The influence of relative slip range and contact material on the fretting fatigue properties of 3.5NiCrMoV rotor steel has been investigated. Two generator rotor slot wedge materials, 1CrMo steel and 2014A aluminum alloy, were employed as contact materials. The results indicate that the observed relationships between both relative slip range and contact material and the fretting fatigue strength of 3.5NiCrMoV steel can be fully rationalized in terms of surface fretting contact stresses. Relative slip range and contact material are themselves of secondary importance. Fretting fatigue tests have been interrupted and specimens broken open, demonstrating that small cracks can initiate by fretting at stresses considerably below the fretting fatigue limit. The size of these nonpropagating cracks is related to the frictional and normal forces at the fretting contact and is independent of externally applied stresses and relative slip range, at least over the range of conditions investigated. (Edited author abstract). 14 Refs.

**092045 INVESTIGATION ON THE FLOW FIELDS AND POWER MECHANISM OF A SAVONIUS ROTOR. (FLOW VISUALIZATION BY A SMOKE-WIRE METHOD).** Unsteady flow fields around a Savonius rotor and its power mechanism are studied by a flow visualization experiment for various rotor angles and tip-speed ratios. For small tip-speed ratios, the rotor receives a corotating torque mainly due

to the difference of the drag on both the blades. As the tip-speed ratio increases a Coanda-like flow pattern is formed on the convex side of an advancing blade, and the corotating torque is expected by the induced lift, though the torque due to the difference of the drag decreases. The power performance of a Savonius rotor can be explained reasonably by the flow visualization results. (Author abstract) In Japanese. 16 refs.

## Forming

**092046 PROPERTIES OF LARGE A286 ALLOY ROTOR FORGING.** This paper describes the preliminary investigation, manufacture, and properties of a trial A286 rotor forging, to establish the manufacturing process of large A286 alloy forging planned to be applied to rotor material used at temperatures above 593°C for ultra-supercritical steam turbines. First, Ti contents and heat treatment conditions were investigated to improve the creep rupture ductility. Subsequently, a large trial A286 alloy rotor forging of 850mm barrel diameter, weighing 8.9 tons, was manufactured from a 16 ton electro slag remelted ingot, and its properties were tested. Chemical composition of the trial A286 alloy rotor forging shows little variation, and its grains are fine and uniform (2.5-3.5 in ASTM G.S.No.). Its mechanical properties are comparable to those of small forgings with a conventional Ti content, reported previously. The good mechanical properties are caused by relatively lower Ti content and application of three-step aging treatment. (Author abstract) 7 refs.

## Inspection

**092049 TURBINES MISSILES ASSESSMENT.** In a study commissioned by the U.S. Nuclear Regulatory Commission (NRC), Pacific Northwest Laboratory evaluated the costs and benefits of modifying regulatory requirements in the area of the turbine rotor design reviews and inspections. The basis for the analysis was presented in the Regulatory Analysis Guidelines and in the Handbook for Value-Impact Assessment. The effects of selected modifications to regulations were evaluated in terms of public risk and costs to industry and the NRC. The results indicate that substantial savings in operating costs may be realized by changing the interval of turbine rotor inspections. (Author abstract) 19 refs.

## Mathematical Models

**092051 CONICAL ELEMENT FOR FINITE ELEMENT ROTOR DYNAMICS.** A conical beam element for rotor dynamic analysis is proposed. The element, with circular or annular cross-section, is based on the Timoshenko beam theory. It has two complex degrees of freedom at each node. The procedure for the computation of the stiffness, mass, gyroscopic damping matrices and of the unbalance vector is fully described. (Author abstract) 8 refs.

**092052 DYNAMICS OF VISCOELASTIC ROTORS.** The stability of two mathematical models of a viscoelastic rotor - a 2-parameter solid model and a 3-parameter solid model - is investigated by means of a complex Routh-Hurwitz analysis. While the 2-parameter model possesses a certain well-known stability limit for the angular velocity, it is shown that the 3-parameter model has two stable regions for the angular velocity, separated by an unstable one, if the coefficient of external damping is less than a special value  $d_c^*$ . For external damping coefficients greater than  $d_c^*$ , the rotor is stable for all angular velocities. It is interesting that the stabilizing value  $d_c^*$  does not depend on the coefficient of internal damping. Moreover, the general result for the 3-parameter model is shown to include the following special cases: small external and internal damping coefficients, and very large internal damping coefficient. **092054 ANALYSIS OF THE ACOUSTIC PLANFORM METHOD FOR ROTOR NOISE PREDICTION.** This study analyzes the acoustic planform method as an alternative to using the equation of Ffowkes Williams and Hawkings for predicting transonic and supersonic rotor noise. The studied method avoids the singularity encountered when the noise source travels towards the observer at sonic velocity. It introduces the necessity for computing acoustic planforms and integrating over them. Results are presented for a rotating, rectangular, monopole surface with supersonic tip velocity. These computations show a decrease in peak acoustic pressure as the tip speed increases beyond a critical supersonic Mach number. The results provide an explanation for some experimental data and some guidelines for proceeding on to the prediction of actual rotor noise. (Author abstract) 6 refs.

## Optimization

**092055 OPTIMAL DESIGN OF SQUEEZE FILM DAMPERS FOR FLEXIBLE ROTOR SYSTEMS.** Optimization techniques are employed to design squeeze film dampers for minimum transmitted load to the bearing and foundation in the operational speed range. The rotor systems are modeled by finite element formulation. The maximum transmitted load in the operational speed range is the objective function that is minimized using mathematical nonlinear programming (NLP) techniques. The damper design parameters are the radius, length, and radial clearance. Stability of the equilibrium solutions are investigated in the design procedure. Design derivatives have been determined in closed form expression without resolution of the inherently nonlinear problem. A parametric study of the transmitted force is carried out to show the influence of damper parameters on the response and to demonstrate the merits of applying optimization techniques in damper design. Two numerical examples are presented that illustrate the effectiveness of optimizing squeeze film damper designs for reducing transmitted load. (Author abstract) 33 Refs.

**092056 INFLUENCE OF REYNOLDS NUMBER ON PERFORMANCE MODELING OF HORIZONTAL AXIS WIND ROTORS.** This paper investigates the influence of Reynolds number on performance modeling of horizontal axis wind rotors. A procedure for accounting for Reynolds number effects on airfoil section models was developed and implemented for NACA 0012 and NACA 4415 profiles. For symmetrical airfoils, this effect on performance was only significant for low tip-speed ratios, while cambered airfoils were affected more uniformly at all operating conditions. Changes in performance were induced by parametric variations of wind speed, rotor scale,

and rotor generating mode using the Reynolds number dependent section models. Results show that wind speed variations are more significant for smaller rotors at lower wind-speeds, and section models represented at only a single Reynolds number are more suitable for the analysis of constant RPM rotors. ## Seals

**092057 THEORY VERSUS EXPERIMENT FOR THE ROTORDYNAMIC COEFFICIENTS OF LABYRINTH GAS SEALS. PART I: A TWO CONTROL VOLUME MODEL.** The basic equations are derived for a two-control-volume model for compressible flow in a labyrinth seal. The recirculation velocity in the cavity is incorporated into the model for the first time. The flow is assumed to be completely turbulent and isoenergetic. The wall friction factors are determined using the Blasius formula. Jet flow theory is used for the calculation of the recirculation velocity in the cavity. Linearized zeroth and first-order perturbation equations are developed for small motion about a centered position by an expansion in the eccentricity ratio. The zeroth-order pressure distribution is found by satisfying the leakage equation while the circumferential velocity distribution is determined by satisfying the momentum equations. (Edited author abstract). 23 Refs.

**092058 THEORY VERSUS EXPERIMENT FOR THE ROTORDYNAMIC COEFFICIENT OF LABYRINTH GAS SEALS. PART II: A COMPARISON TO EXPERIMENT.** An experimental test facility is used to measure the leakage and rotordynamic coefficients of teeth-on-stator labyrinth gas seals. The test results are presented along with the theoretically predicted values for the two seal configurations at three different radial clearances and shaft speeds to 16,000 cpm. The test results show that the theory accurately predicts the cross-coupled stiffness for both seal configurations and shows improvement in the prediction of the direct damping for the teeth-on-rotor seal. The theory fails to predict a decrease in the direct damping coefficient for an increase in the radial clearance for the teeth-on-stator seal. (Author abstract). 15 Refs.

**092059 STABILITY LIMITS OF FLEXIBLE ROTOR SUPPORTED BY JOURNAL BEARINGS WITH PRESSURE DIFFERENCE BETWEEN BOTH ENDS (2ND REPORT, THEORETICAL ANALYSIS - PART 2).** The effects of mean radial clearance and bearing length on the stability threshold speed are investigated. The dynamic Reynolds equation is applied to the system, and numerically solved with the pressure drop mainly due to the axial acceleration of the oil at the inlet end of journal bearing being taken into account. The stability threshold speed is obtained by linearizing the equation of motion about the equilibrium and applying the Birstow-Hitchcock method to solve the characteristic equation. The stability threshold speed increases with pressure difference except for the range of low pressure difference regardless of the dimensions of mean radial clearance and bearing length. (Edited author abstract) In Japanese. 1 ref.

**092060 STABILITY OF A RIGID ROTOR SUPPORTED ON FLEXIBLE OIL JOURNAL BEARINGS.** This investigation deals with the stability charac-

teristics of oil journal bearings, including the effect of elastic distortions in the bearing liner. Graphical results are presented for (1) steady-state load, (2) stiffness and damping coefficients, and (3) the stability. These results are given for various slenderness ratios, eccentricity ratios, and elasticity parameters. The lubricant is first assumed to be isoviscous. The analysis is then extended to the case of a pressure-dependent viscosity. It has been found that stability decreases with increase of the elasticity parameter of the bearing liner for heavily loaded bearings. (Author abstract) 16 refs.

**092062 STABILITY OF A RIGID ROTOR SUPPORTED BY AEROSTATIC JOURNAL BEARINGS WITH CIRCULAR SLOT RESTRICTORS (ON THE DOUBLE-ROW ADMISSION BEARING).** This paper discusses the stability of a rigid rotor supported by double-row admission journal bearings with circular slot restrictors. In the theoretical analysis, the energy loss at the outlet of the slot is taken into account because the gas flow is subject to a rapid change in direction, and here, the energy loss coefficient is determined experimentally. It is found that a better agreement between the theoretical and experimental results for the threshold of instability can be obtained by considering the energy loss. Furthermore, in this paper, it is shown experimentally that an aerostatic journal bearing with circular slot restrictors has higher stiffness and higher stability than a conventional point source bearing with inherently compensated feeding holes. (Author abstract) 5 refs.

**092065 STRESS-STRAIN STATE AND BEARING STRENGTH OF A SEPARATOR ROTOR MADE OF HARDENED COMPONENTS.** The authors study the stress-strain state and the bearing strength of a self-discharging separator rotor having a diameter of 500 mm, made of components which have gone through a hardening cycle. We investigated three variants of the rotor of identical design, differing in the materials used for the body components, which were austenitic-class steels 06Kh17N13M3-VD and ALIII-23-43-02 and austenitic-ferritic class steels. The stress-strain state of a rotor was studied by the numerical method of finite elements for an axisymmetric problem. As a result of the calculations, we obtained the components of displacements and stresses, and also the main stresses at the nodal points. Strength was evaluated by analyzing the equivalent stresses determined by the fourth theory of strength. The highest stresses act on nodes 148 and 336 and amount to 195 and 160.7 MPa, respectively. 8 refs.

## Structural Analysis

**092067 DYNAMICS OF THE ROTOR SYSTEM WITH A TORSIONAL CRACK (A QUALITATIVE ANALYSIS USING A SIMPLE ROTOR MODEL).** In this study, a qualitative analysis of the dynamics of a rotor system with a torsional crack that grows at an angle of 45 degrees toward the axis of the shaft is presented. On the assumption that the bending stiffness of the shaft changes synchronously with the open-close behavior of the crack caused by the torsional vibration of the shaft, the equation of motion of the simple rotor with a torsional crack is represented by a differential equation with parametric excitation on the coordinate system rotating at the operation speed of the rotor. The solution of the equation shows that the steady-state response of the rotor system with the torsional crack contains the frequencies represented by  $m\Omega + n\Omega_T$ ;  $m = 1, 2$ , and  $N = 0, 1, 2, \dots$ , where  $\Omega$  is the operation speed of the rotor, and  $\Omega_0$  is the frequency of torsional vibration of the shaft. (Author abstract). 6 Refs. In Japanese.

**092068 AMPLITUDE-FREQUENCY ANALYSIS OF THE MOTION OF MULTIPLE-IMPELLER ROTORS WITH A VIEW TO THE EFFECT OF THE LUBRICANT LAYER OF THE BEARINGS.** To determine the amplitude-frequency response of rotors, a mathematical model was suggested previously. Using this as a basis, a computer program was developed. An example is used to illustrate the program's capabilities. It is shown that this program can be used for analyzing the dissipative system consisting of a rotor and supports; it increases the accuracy of the calculation of the critical angular velocities, and provides the designer with much wider possibilities for a comprehensive analysis of the dynamics of the rotor. The program KS-ID may also be used for the theoretical analysis of flexible rotors of pumps, centrifuges and other machines. 3 refs.

**092069 HOLOGRAPHIC RAPID CONTROL OF VIBRATION FREQUENCIES OF ROTORS OF COMPRESSED-GAS AGGREGATES.** The rotors of turbo-compressed-gas aggregates operate under dynamic loads; this places strict requirements as to the precision of the determination of vibration frequencies. To overcome the shortcomings of current techniques, the authors used contact-free optical approaches, based on the inversion of the contrast of the interference bands and reduction in visibility of vibrating sections. The stand for the determination of the frequencies of natural vibrations of the rotor includes a module for the excitation of the rotor and an optical module for the recording and reconstruction of the holograms. The fact that the sensitivity of holographic interferometry can be adjusted by changing the angle  $\beta$  and consequently the number of interference lines on the object and that the vibrations can be observed visually, gives high reproducibility and precision to the test. The time required for a rapid test of the rotor is less than two hours. The tests based on the rapid holographic control of the vibration frequency characteristics lead to the development of a rotor design which gives the required efficiency and long life to the machine. The use of the turbo-compressed-gas aggregates in air liquefaction plants has confirmed the validity of the design solutions. 5 refs.

**092072 DYNAMICS OF THE UNBALANCED ROTOR IN MULTICENTER SLIDING JOURNAL BEARINGS WITH NONISOTHERMAL LUBRICA-**

**TION.** An algorithm is proposed for solution of a nonlinear, nonstationary hydrodynamic problem of lubricant flow in multicenter sliding bearings with allowance for thermal processes. The reliability of the mathematical model used and its implementation procedure are confirmed experimentally. It is found that the linear theory of small perturbations is not accurate enough for calculation of the vibrations of rotors in multicenter bearings of high-speed turbomachines. Allowance for nonisothermal lubricant flow makes it possible to improve the path traced by the center of the journal and the minimum lubricant-film thickness, and to determine maximum lubricant temperature. (Author abstract) 7 refs.

Maksimov, V.A.; Mozhanov, V.V. *Sov Mach Sci* n 3 1987 p 87-91.

**092073 ROTATION OF A ROTOR BY MEANS OF AN ELASTIC ROD UNDER THE ACTION OF VIBRATIONS DURING SHIPMENT.** During shipment of machines with rotors mounted in antifriction bearings, these bearings are often damaged by fretting corrosion. This phenomenon develops under conditions such that the force acting on the bearing is quite high and the relative displacements of the rolling bodies and races are limited. Devices that rotate the rotor during shipment and provide for a supply of lubricant to the contact zone between the rolling bodies and the races are used to prevent bearing damage. One of the simplest and most effective protective devices is the elastic-rod system. In this paper the authors determine the regions of existence of various rotation regimes in parameter space and the shaft rotation frequency  $\Omega$ , when rotation occurs without separation from the rod and investigate this frequency as a function of the parameters of the device. Since the rotation frequency has little influence on the effectiveness of protection, the authors concentrate their attention on the conditions under which rotation occurs. (Edited author abstract) 5 refs.

**092074 HIGH ORDER SUBHARMONIC RESPONSE OF HIGH SPEED ROTORS IN BEARING CLEARANCE.** Subharmonic vibration refers to the response of a dynamic system to excitation at a whole-number multiple ( $n$ ) of its natural frequency by vibrating asynchronously at its natural frequency, that is, at  $(1/n)$  of the excitation. The phenomenon is generally associated with asymmetry in the stiffness vs. deflection characteristic of the system. It may be characterized as the 'bouncing' of the rotor on the surface of the stiff support, energized by every  $n$ th unbalance impulse prior to contact. Second, observed in high speed rotating machinery with such an asymmetry in the bearing supports. An incident is reported where 8th and 9th order subharmonic vibration responses have been observed in a high speed rotor. A simple but exact computer model of the phenomenon has been evolved based on the numerical integration of a finite difference formulation. (Edited author abstract) 6 refs.

**092075 SPECIAL CASE OF CRITICAL SPEED OF RIGID ROTORS WITH ANISOTROPIC SUPPORTS.** The critical speed of vertical rigid rotors, elasticity supported at both ends and having an angular difference between the principal axes of elasticity at the lower support and that at the upper, has been investigated. Such a rotor system is found in machinery in which the support stiffness is much softer than that of the shaft, such as a centrifugal separator. The critical speed generally depends on the angular difference, but it is found that the critical speed becomes independent of the angular difference when the rigid rotors satisfy a special condition. The physical explanation for this special case is given. Finally, such a special condition for overhung rotors is also considered. (Author abstract) 3 refs.

**092076 VIBRATION AMPLITUDES OF MISTUNED BLADES.** Due to the mistuning effect, the nominally identical blades on a rotor are forced to vibrate with greatly unequal amplitudes under certain circumstances. It is, therefore, desirable to have the capability of predicting the highest responding blades so that such blades may be instrumented during engine tests. Good agreement is obtained when the results of this study, which is based on a model with structural coupling, are compared with those of other investigators utilizing models with aerodynamic and structural coupling. It is concluded that if the primary resonance being excited is not in a 'crossover' zone, the highest responding blades are most likely to be those with extreme mistuning. (Edited author abstract) 21 refs.

**092078 STABILIZATION BY ELECTROMAGNETIC DAMPER FOR CONTAINED LIQUID INDUCED ROTOR VIBRATION.** It is a well-known phenomenon that unstable rotor vibration occurs when rotors, partially filled with liquid, are rotated through a certain range of rotational speeds. This type of self-excited vibration appears in large-scale continuous flow ultracentrifuges, due to heavier liquid forming laminations with greater weight density. The unstable vibration results from a forward whirl rotor motion. An electromagnetic bearing control, reacting to detection of the rotor displacement, can produce particular damping force characteristics as are required for stabilization. Our control technique features an additional cross coupling network between  $x$  and  $y$  directional channels. This is equivalent to the damping effect generated by the cross stiffness of the bearing reaction:  $K_{xy}$  and  $K_{yx}$ . The sign of the cross stiffness especially depends upon the whirl direction. This optional control strategy using the cross effect is successfully experienced by combating unstable flow induced forward rotor vibration. (Author abstract) 8 refs. In Japanese.

**092079 ROTOR ACTIVE 'ANTI-SWIRL' CONTROL.** Rotor self-excited vibrations due to solid/liquid interaction, such as occurring in seals, can easily be reduced or eliminated by controlling fluid circumferential velocity. This is known as 'anti-swirl' technique. An active 'anti-swirl' control system for rotating machines is described in the paper. While mainly controlling rotor self-excited vibrations, this active control system reduces also rotor lateral vibrations caused by other factors (such as unbalance), by increasing the system effective damping. (Author abstract) 23 refs.

**092080 DATA DEPENDENT SYSTEMS APPROACH TO MODAL ANALYSIS. PART II: APPLICATION TO STRUCTURAL MODIFICATION OF A DISC-BRAKE ROTOR.** The Data Dependent Systems (DDS) methodology is used to determine the modal parameters of a disc-brake rotor. The rotor, due to its symmetry, causes the vibration induced disc-brake squeal phenomenon. This paper presents results from an experimental investigation to show how structural modification can be used to change the modal parameters of the rotor. The modal parameters from both the DDS method and from a Fourier analyzer based modal analysis package are presented. Each rotor was modeled with 60 points on three equally spaced diameters. For an unmodified free-free rotor (resting on packing foam) the DDS results indicate that a 60th order model was required, whereas a structurally modified disc-brake rotor required a 76th order model. The results indicate how the disc-brake rotor can be modified to reduce the squeal propensity in selected frequency ranges. (Author abstract) 12 refs.

**092081 USE OF SMOOTH BENDING MOMENT MODES IN HELICOPTER ROTOR BLADE VIBRATION STUDIES.** The application of a special type of assumed mode in problems of helicopter rotor blade vibration is described. These assumed modes thus have a smoothly varying bending moment distribution, as actually occurs on the rotor blade. Similar types of assumed mode are used to represent twisting motion. Natural frequencies and normal mode shapes for a rotating helicopter rotor blade are evaluated by using these special assumed modes. The results are seen to compare favorably with results obtained more conventionally and with a more detailed mathematical model. (Edited author abstract) 7 refs.

**092082 COUPLED LATERAL-TORSIONAL VIBRATION OF A ROTAR SYSTEM TRAINED BY GEARS (8TH REPORT: THE RELATION BETWEEN VIBRATIONS AND GEAR NOISE).** There are many papers dealing with the vibrations of a geared-rotor system. Recently, the dynamic behavior of the geared system has been analyzed. However many of them have studied only the dynamic load on the tooth, or have left the tooth rigidity and the flexural rigidity of the shaft out of consideration. But it is important to consider the effect of coupled lateral and torsional vibration. This study presents the experimental results of the vibrations and the noise of the geared-rotor system with a journal bearing. The following results are obtained. In response to angular acceleration in the gears, there are some resonant peaks caused by the excitation relating to the mesh frequency. And some other resonances appear in response to the lateral vibration and the torsional vibration caused by the mesh frequency excitation. The gear noise is concerned mainly with the vibration of the tooth. (Author abstract) 4 refs. In Japanese.

**092084 FEMROT - EIN BAUSTEIN FUER BE-RECHNUNGEN ZUR ROTORDYNAMIK. [FEM-**

**ROT - a Module for Calculations about Dynamics of Rotor].** FEMROT is a program of finite elements for static and dynamic calculations at rotor structures of machining and processing machine building. A survey is given about model generation and solvable calculation problems. By connection with the program TANDYS further essential problems of rotor dynamics can be solved. As examples for using FEMROT types of vibration of two rotor systems are stated. (Author abstract) In German. 5 refs.

Waldeck, D. (Technische Univ Karl-Marx-Stadt, East Ger). *Maschinenbautechnik* v 37 n 5 May 1988 p 238-240.

**092085 ACTIVE VIBRATION CONTROL OF FLEXIBLE ROTOR SUPPORTED BY ACTIVE CONTROL BEARINGS (2ND REPORT, QUASI-MODAL CONTROL BASED ON EXPERIMENTAL MODAL ANALYSIS).** Vibration of a flexible rotor is reduced by a quasi-modal control method with only velocity feedback. If a mathematical model includes much error of parameter identification, much cumulated error in feedback gains result from an incorrect equation of motion. In these cases, the responses with control are not improved as we expected, or the control system becomes unstable for the worst case. Therefore, in this paper, the control system is designed based on an experimental modal analysis instead of a mathematical model. The first mode to the fifth mode of the flexible rotor supported by linear actuators through bearing housings are controlled by only two sensors and two actuators in the experiments. The maximum amplitudes of unbalance responses are reduced, and the self-excited vibrations caused by dry friction are prevented by the quasi-modal control. (Author abstract). 5 Refs. In Japanese.

**092086 STABILITY OF CRACKED ROTORS IN THE COUPLED VIBRATION MODE.** A transverse surface crack is known to add to a shaft a local flexibility due to the stress-strain singularity in the vicinity of the crack tip. This flexibility can be represented, in the general case by way of a 6x6 compliance matrix describing the local flexibility in a short shaft element which includes the crack. This matrix has off-diagonal terms which cause coupling along the directions which are indicated by the off-diagonal terms. In addition, when the shaft rotates the crack opens and closes. Then the differential equations of motion have periodically varying stiffness coefficients and the solution can be expressed as a sum of harmonic functions of time. A method for the determination of the intervals of instability of the first and of second kind is developed. The results have been presented in stability charts in the frequency vs. depth of the crack domain. (Edited author abstract). 10 Refs.

**092087 CONTROL OF ROTOR AERODYNAMICALLY FORCED VIBRATIONS BY SPLITTERS.** A mathematical model is developed to demonstrate the potential benefit of splitter blades as a passive control mechanism for the flow-induced forced response of supersonic turbomachine rotors. The splitters introduce both aerodynamic and structural detuning and also provide a large measure of control of the location of the Mach wave full-chord airfoil and splitter intersections. The level of aerodynamic detuning is associated with the relative locations of the splitters in the full-chord airfoil passages, with the level of structural detuning a function of the ratio of the natural frequencies of the splitters to that of the full-chord airfoils. (Edited author abstract). 11 Refs.

## Wear Resisting

**092088 EFFECT OF THE STRUCTURE OF SURFACING MATERIALS OF ROTOR COUPLINGS ON WEAR OF PUMP-COMPRESSOR PIPES.** An investigation was conducted into the effect of the structure of hard alloys on the wear of the surface of a pipe in order to select efficient surfacing materials and their deposition technology. Microscopic analysis showed that the friction surfaces of the pump-compressor pipes in contact with rods hard faced with sormite No. 1 and VZK satellite contain deep grooves and scratches, in contrast to the smooth and flat friction surface of pipes with no visible damage tested in pairs with the rods hard faced with S-6 satellite and Az-4 alloy. Experimental results show that rod couplings should be hardfaced with hard alloys with a homogeneous fine-dispersed structure where the hardness of the matrix differs only slightly from that of the inclusions. 3 refs.

**092091 PROCEEDINGS FROM THE INTERNATIONAL RUBBER CONFERENCE: IRC 86.** This conference proceedings contains 126 papers in three volumes. Of these 37 papers are short papers, and 28 are in the abstract form only. Topics covered include: rubber chemistry; mixing and blending; rubber physics; rubber processing; dynamic properties; advances in tire manufacturing and properties of tires; testing and control equipment for rubber manufacture and processing; reinforcements to rubber and rubber products and properties of these composites; economy and strategy for the future rubber industry; rubber components for machinery; raw materials and compounding; study of chemical reactions and kinetics of these reactions during rubber compounding and processing and effects of various chemicals and operating parameters on properties of rubber and rubber compounds; and calculation and mathematical techniques for determining properties and behavior of rubber products. Technical and professional papers from this confer-

ence are indexed and abstracted with the conference code no. 11133 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

## Acoustic Emission Testing

**092092 KOERPERSCHALL IN GUMMIFEDERN - EINE UNTERSUCHUNG.** [Structure Born Noise Radiating from Rubber - Springs An Analysis]. When considering the moduli of compression and of elasticity in shear as well as their frequency and temperature characteristics, elastomers give rise, at room temperature and at acoustic frequencies, to expect sound velocities permitting the formation of standing waves. In this test, it is shown that for shear and compressional waves, the typical resonance phenomena can be detected by the formation of standing waves. When frequency and amplitude characteristics of the elastomer used for the spring are known, the frequencies of standing waves can be rated for vibrational excitations as known. From this, it is derived that for nondirectional excitations of vibration, the shear waves of all springs are to be considered. (Edited author abstract) 8 refs. In German.

**092095 RUBBER ADDITIVES DERIVED FROM GUAYULE RESIN.** The commercial viability of natural rubber from the desert shrub guayule will depend on production of high-value byproducts to offset farming and processing costs. Guayule resin, the nonrubber extractables, can be chemically modified to produce solid derivatives which enhance the physical and chemical properties of rubber compositions. These derivatives affect sulfur vulcanization in a manner related to the nature of the modifying agent. Sulfurized guayule resin reduces vulcanization hysteresis. Guayule resin condensed with polyamines or amine-terminated polyethers improves green strength and vulcanizate tear strength. (Author abstract) 17 refs.

**092099 AGING OF EPDM RUBBER.** The effect of oxidative and thermal aging of EPDM raw rubber and rubber vulcanizate on gelation, network structure, and technical properties has been studied over a wide range of temperatures and times of aging. Three grades of EPDM having different types of diene have been considered. The kinetics of aging of both raw rubber and vulcanizates has also been reported. Different network structures have been produced due to different reactivity of termonomers. Cross-link density, cross-link efficiency, polysulfidic linkage, zinc sulfide sulfur, combined sulfur, free sulfur, and sulfur inefficiency change with aging time and temperature. The number of polysulfidic cross-links decreases continuously with increase in time or temperature of aging. There is no definite trend in other structural features. (Edited author abstract) 22 refs.

**092100 EFFECT OF AGEING ON CRITICAL CUT LENGTH AND MORPHOLOGY OF FRACTURE SURFACE IN TENSILE RUPTURE OF NATURAL RUBBER.** Variation of tensile strength with flaw sizes has been studied both for unaged and aged natural rubber (NR) gum vulcanizates (aged up to 150°C). A precut of varying lengths is given at the center of the tensile specimens. The morphology of the fracture surfaces has also been reported. A critical cut length is observed for NR vulcanizates. There is an increase in the critical cut length ( $l_c$ ) on ageing. The sharp fall of tensile strength at

the critical cut length, however, gradually diminishes. On prolonged ageing, no critical cut length is observed. A mathematical model has been made to explain the behavior of the critical cut length of NR that there is a change in the mechanism of rupture above the  $l_c$ . Below the  $l_c$ , it is a cut growth process and fracture is originated from natural flaws/nicks and proceeds towards the precut at the center. However, for samples with precut greater than the  $l_c$ , the fracture is mainly a tearing phenomena initiating from the given precut. A quantitative correlation between the tensile strength and the distance between crack lines/tear lines has been found. (Author abstract) 11 refs.

## Amorphous

**092101 X-RAY CDF STUDY ON THE BEHAVIOUR OF THE AMORPHOUS CHAIN UNDER EXTENSION.** The behavior of the amorphous chain in vulcanized natural rubber (NR) and styrene-butadiene rubber (SBR) under extension is studied by means of the cylindrical distribution function (CDF) derived from wide angle X-ray scattering (WAXS). In the case of the highly stretched vulcanized NR where the orientation-induced crystallization took place, the observed WAXS intensity was separated into a crystalline peak component and a broad amorphous one from which the CDF was obtained. The CDF calculated from the broad component shows that some of the amorphous segments of the highly stretched vulcanized NR are extended as fully as the crystalline chains and that the fraction of the segments increases with increasing extension. In the case of SBR, such fully stretched segments as in the case of the vulcanized NR show higher degree of an interchain packing order than those in the vulcanized NR. (Author abstract) 15 refs.

## Antioxidants

**092102 ACTIVITY OF PHENOLIC ANTIOXIDANTS IN RUBBER APPLICATIONS - THEORY AND PRACTICE.** A large number of phenolic antioxidants are presently available, from the low cost monophenols to the highly expensive polyphenols. The selection of an antioxidant from this range is not always easy. The purpose of this paper is to give some rational grounds for this selection. This will be achieved in two different and complementary ways: (1) theoretically by examining the relationship between the activity of phenolic antioxidants and their chemical structure and hence predicting their performance; and (2) practically by comparing phenolic antioxidants in typical rubber applications. This approach shows the value of the theory, but also its limits due to the nature of the media in which the products are used. (Edited author abstract) 15 refs.

**092104 DYNAMIC MECHANICAL PROPERTIES OF NR-HDPE BLENDS.** A study of the dynamic mechanical properties of natural rubber (NR)-high-density polyethylene (HDPE) blends is reported in the present paper. The effects of blend ratio, dynamic crosslinking, and carbon black filler on the storage, loss moduli, and  $\tan \delta$  are examined. The dynamic mechanical properties of pure HDPE are reported for comparison. 27 refs.

Akhtar, S. (Indian Inst of Technology, Kharagpur, India); Bhagawan, S.S. *Rubber Chem Technol* v 60 n 4 Sep-Oct 1987 p 591-599.

**092105 CO-VULCANIZATION IN NR/EPDM BLENDS.** A novel cure system made of sulfur and peroxide curatives catalyzed by MBTS (mercaptobenzothiazole disulfide) and DPG (diphenylguanidine) was found to improve co-vulcanization of EPDM (ethylene propylene diene monomer) dispersion in NR (natural rubber). This cure system showed a two fold improvement in tensile strength of NR/EPDM vulcanizate over that of a conventional sulfur cure system, excellent heat aging resistance static ozone resistance. The presence of peroxide in the cure system did not show any detrimental effect on NR/EPDM vulcanizate cured in hot air autoclave when a proper level and type of peroxide and other cure constituents were used. (Author abstract) 15 refs.

**092106 RHEOLOGICAL BEHAVIOUR OF 1,2 POLYBUTADIENE-NATURAL RUBBER BLENDS.** The rheological behavior of thermoplastic 1,2 polybutadiene-natural rubber (1,2 PBD-NR) blends has been investigated in terms of effects of blend ratio, filler loading and temperature on viscosity, die swell and flow behavior index ( $n'$ ). The viscosities of the blends were found to obey a logarithmic additivity rule up to a shear stress of  $1 \times 10^5$  Pa. At a given shear stress, HAF black imparts higher viscosity to the blends than clay does. The viscosities of the 50/50 blend at different loadings of clay merge into a single curve when corrected on the basis of volume fraction of polymer. The activation energies of flow indicate that the clay-filled blend (50/50) is more temperature sensitive than the carbon black-filled blend. Die swell was found to increase with shear rate and decrease on addition of filler. The die swell data exhibit maxima/minima at certain blend ratios, and have been explained on the basis of extrudate morphology. (Edited author abstract) 13 refs.

Bhagawan, S.S. (Indian Inst of Technology, Kharagpur, India); De, S.K. *Plast Rubber Process Appl* v 9 n 1 1988 p 37-45.

**092107 UNTERSUCHUNGEN ZUM WANDGLEITVERHALTEN VON KAUSCHUK-MISCHUNGEN AN EINEM HOCHDRUCK-KAPILLAR-VISKOSIMETER.** [Investigation into the Wall Slip Behavior of Rubber Blends with a High Pressure Capillary Viscometer]. To predict the processing of rubber for better process control the knowledge of the flow properties is necessary. The rheological behavior includes anomalous flow such as wall slip. An investigation of the wall slippage of rubber compounds based on ethylene-propylene-diene-rubber (EPDM) is presented. The effect of filler and softener is particularly taken into account. The wall slippage is estimated by a method suggested by M. Mooney. As a result can be mentioned, that wall slipping EPDM blends at low pressure slide like a solid on the capillary wall with a friction behavior close to Coulombs law. At high pressure the rubber blends behave like a liquid with a pressure independent wall slip. (Edited author abstract) 25 refs. In German.

Jepsen, C.; Raebiger, N. *Kautsch Gummi Kunstst* v 41

n 4 Apr 1988 p 342-352.

**092108 BLENDS OF DISSIMILAR RUBBERS - CURE-RATE INCOMPATIBILITY.** The mechanical properties of a vulcanizate of a blend which comprises both a high-diene rubber such as NR and an ozone-resisting concentration (at least 30 to 40 wt.% of the polymers) of EPDM can be greatly improved if the EPDM is chemically modified by the action of maleic anhydride. The effect of the EPDM modification of the vulcanizate properties is to give increased tensile strength, improved fatigue resistance, and reduced hysteresis and set. The excellent ozone resistance which results from the presence of about 30 to 40% unmodified EPDM is also obtained when the modified EPDM is used. Good results are obtained when only 1 to 2% (as a wt.% of EPDM) of maleic anhydride is used in the modification of the EPDM. Good results are obtained when only part of the EPDM is modified by the action of maleic anhydride. However, best results are obtained when all of the EPDM is treated with maleic anhydride. 21 refs.

Coran, A.Y. (Monsanto Chemical Co, Akron, OH, USA). *Rubber Chem Technol* v 61 n 2 May-Jun 1988 p 281-292.

**092109 TECHNIQUE FOR MEASURING THE CROSSLINK DENSITIES IN BOTH PHASES OF A VULCANIZATE BLEND.** This paper reports on the use of freezing point depressions used in conjunction with swelling experiments to examine the crosslink densities in vulcanizate blends. Natural rubber (SMR 20) (NR) and polybutadiene Buna-CB11 (BR) were cured with BDH dicumyl peroxide (DCP) and various accelerated sulfur formulations using tetramethyl thiuram disulphide (TMTD) as accelerator. Vulcanizates were swollen in cyclohexane and the gel solvent frozen by cooling the swollen vulcanizate in a Du Pont differential scanning calorimeter (DSC) at 5°C/min. The magnitude of the depression of the freezing point of a solvent in a swollen vulcanizate is dependent on the crosslink density. It is shown that use of such measurements, coupled with the conventional swelling technique, allows the crosslink density in both phases of a vulcanized blend to be determined. (Edited author abstract). 20 Refs.

## Bonding

**092110 BIDEN VON GUMMI AUF SUBSTRATE.** [Bonding Between Rubber and Substrate]. This paper demonstrates the dependence of the bond quality between elastomers and materials with high elasticity moduli on physical and chemical factors. They form the basis for production specifications which guarantee reproducible manufacture of high-grade articles if applied with high precision and discipline. (Edited author abstract). 21 Refs. In German.

Haertel, Volker (Metzeler GmbH, Munich, West Ger). *Gummi Fasern Kunstst* v 41 n 6 Jun 1988 8p.

## Chemical Analysis

**092111 DETERMINATION OF CARBON BLACK IN RUBBER VULCANIZATES BY METATHESIS DEGRADATION.** The amount of fillers such as carbon black occurring in rubber vulcanizates can be determined in various ways. In the present paper, the authors investigate whether metathesis degradation of rubbers (e.g., 1,4-polybutadiene crosslinked by sulfur or dicumyl peroxide) is also suited to determine carbon black fillers. The crosslinked matrix is degraded to low molecular weight products with an excess of a low molecular weight olefin. Metathesis degradation is carried out with the catalyst  $WCl_6/(CH_3)_2Sn$  at only slightly elevated temperatures (40 or 60°C). The low molecular weight olefin used is the relatively cheap 1-octene, whose boiling point allows working at normal pressure. 7 refs.

*Rubber Chem Technol* v 60 n 4 Sep-Oct 1987 p 600-605.

**092112 HPLC PROCEDURE FOR THE DETERMINATION OF FREE SULFUR IN NATURAL RUBBER FORMULATIONS.** The conventional ASTM method for the determination of the percent of free sulfur is a time-consuming method. Additionally, because of the many steps involved and the necessity of subjective endpoint determination, the data would vary from operator to operator. This lack of precision is detrimental in a quality-control type environment, and a retest can literally hold up production. The HPLC method described is almost totally automated. Sample preparation involves no exposure to such toxic chemicals as formaldehyde, cadmium salts, or glacial acetic acid. Quantitation is a computer operation negating operator to operator variations which can cause up to 20% relative standard deviation. 1 ref.

## Chemical Resistance

**092114 EFFECT OF FRESH WATER AND SEA WATER ON DIFFERENT GRADES OF CREPE RUBBER.** The tendency to absorb moisture and the metal ion concentration in natural rubber vary with the amount of proteins present. Yellow fraction rubber, containing the highest protein content, rapidly absorbs moisture if exposed to water, causing mold contamination and deterioration of the tensile properties of vulcanizates. White crepe rubber, which is made by removing the yellow fraction, contains the least amount of non-rubber constituents and is least affected by sea water or fresh water. (Edited author abstract) 7 refs.

## Crack Propagation

**092119 COMPARISON OF THE LOCUS AND THE EXTRAPOLATION METHODS THAT DETERMINE THE CRITICAL J-INTEGRAL IN THE PRESENCE OF REMOTE ENERGY DISSIPATION.** The locus method of partitioning the energy for crack propagation from the total deformation energy is based on energy release rate interpretation of J-integral. The extrapolation method is based on an assumption that the total energy absorbed can be thought of as the sum of the energies absorbed in the crack tip region and the region away from it, and thus the effect of remote energy dissipation on the critical J-integral value can be eliminated by evaluating the value using the crack tip energy only. A comparison of these two methods is attempted based on the same load-displacement records of a highly deformable thermoplastic rubber, and advantages of the locus method are presented. (Edited author abstract). 12 Refs.

## Crosslinking

**092120 PEROXIDE CROSSLINKING: A STRENGTH/WEAKNESS ANALYSIS VS SULPHUR VULCANIZATION.** The basic mechanisms of peroxide and sulfur crosslinking are described. The kinetics of peroxide crosslinking, decomposition mechanism and products, and choice of proper peroxide are discussed. There are a few limiting factors to peroxide crosslinking, which are mainly related to the fact that the highly reactive free radicals generated are prone to side reactions; the far less aggressive radicals generated in sulphur

vulcanization in general do not give rise to this type of side reaction. 16 refs.

van Drumpt, J.D. (Akzo Chemie America). *Rubber World* v 197 n 6 Mar 1988 p 33-34, 36-41.

**092121 APPLICATION OF STATIC SIMS TO THE STUDY OF RUBBER CROSS-LINKING.** Static SIMS has been used to analyze the sulfur cross-links at the surface of compounded polyisoprene rubbers. Linear relationships were found between the normalized intensities of  $S_1^-$  ions and the total cross-link densities and between the intensities of the  $S_4^-$  clusters and the percentages of the polysulfidic cross-links. (Author abstract). 6 Refs.

## Crystallization

**092122 RHEO-OPTICAL STUDY OF THE INFLUENCE OF ADDITIVES ON CRYSTALLIZATION RATES IN CIS-1,4 POLYISOPRENE.** A rheo-optical study of the influence of additives on crystallization rates in synthetic cis-1,4 polyisoprene (IR2200) at room temperature is presented. Nine different additives at a 1% concentration were examined. This study has found many additives which seem to be effective in enhancing the rate of stress-induced crystallization in IR2200. There is a good relation between enhancement of green strength and fraction of stress-induced crystallinity in IR2200 caused by additives. 20 refs.

**Curing** See Also THERMOPLASTIC ELASTOMERS—Blending.

**092123 CURING RUBBER.** The author discusses the vulcanization of specific elastomers and the influence that the variety and density of cross-links can have on mechanical properties. It is shown that considering the cross-links as mechanical junctures uniting two polymer chains, the effect of their number and their flexibility becomes apparent in a mechanical sense. As an example, tire tread is subject to a range of mechanical abuse and dictates the use of polysulfidic cross-links at a minimum density. Seals, especially O-rings, are usually under compression over a broad range of temperatures. Service conditions dictate thermally stable cross-links (carbon-carbon or carbon-sulfur-carbon) at a high density. Bonded-rubber motor mounts require a density somewhere between that needed for tire treads and O-rings to allow a balance between mechanical life and strain relaxation. 13 refs.

Hertz, Daniel L. Jr. *CHEMTECH* v 16 n 7 Jul 1986 p 444-447.

**092124 COMPARISONS OF METHODS OF STATE-OF-CURE DETERMINATION.** The DSC method of relative state-of-cure determination is preferred due to the ability to use a small irregular sample and because of the short time required to run a test. This method is limited, however, to materials with a sufficiently high heat of vulcanization. The time required to reach 80% conversion at 142°C for Y156B-2 as measured by DSC is 19 minutes. This time to 80% conversion is for reference in comparing test methods only. The Mooney-Rivlin method of relative state-of-cure determination is a useful method for those elastomers which do not lend themselves to the DSC method. The small strain modulus ( $C_1 + C_2$ ) should be used instead of the more rigorous  $C_1$  measurement. The two-solvent technique of the solvent swell method of relative state-of-cure determination is a good procedure for determining X for a solvent-polymer pair. The solvent swell method in general is not recommended for this type of state-of-cure measurement due to poor resolution at higher states-of-cure.

**092126 CHANGES IN THE VISCOSITY AND CURE BEHAVIOUR OF NATURAL RUBBER COMPOUNDS DURING STORAGE AT 20-40°C. PART 2: EFFECTS OF MIXING TEMPERATURE FOR CONVENTIONAL THIAZOLE- AND SULPHENAMIDE-ACCELERATED SYSTEMS.** The effects of mixing temperature on changes in the viscosity and cure behavior of natural rubber compounds during storage at 20-40°C have been studied for compounds containing conventional thiazole- and sulphenamide-accelerated systems. Mill finalization temperature over the range 60-100°C was found to have little effect on scorch and cure performance. The storage-related decrease in state of cure measured by Rheometer torque rise was, however, found to be greater in hot-mixed compound stored at 40°C. (Edited author abstract) 3 refs.

Bristow, G.M. *NR Technol* v 18 Pt 4 1987 p 75-80.

**092127 CURE MODIFICATION OF NR EFFECTED BY THIOAMINES IN THE PRESENCE OF DIBENZOTHAZYL DISULFIDE.** The activating as well as retarding effect of some thioamines, namely, bis(N-oxidiethylene) monosulphide, bis(N-cyclopentamethylene) monosulphide and N-cyclopentamethylene-N'-oxidiethylene monosulphide has been studied in MBTS-accelerated vulcanization in NR. The accelerators formed in the medium from the reaction of thioamine with MBTS bring about cure synergism. The vulcanizates obtained exhibit good age resistance behavior. The thioamine-MBTS combinations also improve the heat resistance of the resulting vulcanizates. (Author abstract) 11 refs.

Das, P.K.; Datta, R.N.; Basu, D.K. *Kautsch Gummi Kunstst* v 41 n 1 Jan 1988 p 59-62.

**092128 STABILIZED CURATIVE BLENDS FOR RUBBER.** Blending of curatives offers several advantages. These include a sharply reduced number of weightings of curative ingredients, reduced weighing costs, reduced dusting and improved cleanliness. These advantages might not be realized with some curative blends. For example, diphenyl guanidine (DPG) could not be blended with sulfenamide accelerators because it reacted chemically with the sulfenamides. This paper shows that aging of curative blends (like S and DPT) sharply reduces the scorch resistance of rubber compounds containing the aged blends. Selected additives will stabilize the blends. Blends were aged at 40°C under dry (28% RH) or humid (92% RH) conditions. Relative humidity (RH) was established with dry- and wet-bulb thermometers. 10 refs.

## Cutting

**092129 TRIM-LOSS MINIMIZATION IN A CREPE-RUBBER MILL; OPTIMAL SOLUTION VERSUS HEURISTIC IN THE 2 (3)-DIMENSIONAL CASE.** The efficiency - waste minimization - of a production planning system (PPS), solving the 3-dimensional cutting problem in a crepe rubber mill, has had to be proved. The authors point out the problem caused by material and production. An algorithm solving these

problems optimally but with comparatively high CPU-time is present. It is shown how a good heuristic for the same problem works. A comparison is made with the heuristic with the optimal solution. Another comparison is made of the presently employed system with the heuristic. (Edited author abstract) 3 refs.

**Deformation** See Also MATERIALS—Deformation; POLYMERS—Mathematical Models; TIRES—Testing.

**092130 VOLUME CHANGE AND GAS TRANSPORT AT UNIAXIAL DEFORMATION OF FILLED NATURAL RUBBER.** The volume dilation of differently filled specimens of natural rubber has been measured using a deformation dilatometer. If the matrix detaches from the filler particles, hollow spaces form. The volume dilatation caused by this effect can be measured and calculated if the material is submerged in a liquid medium. The measured volume dilatation reflects the interaction between filler and matrix. The volume contraction caused by stress-induced crystallization can be recorded clearly only if one uses a liquid as the measurement medium. Due to gas exchange between the sample and its environment and the different gas solubilities in the amorphous and crystalline material no stress-induced crystallization can be detected. At the same time, a possibility opens up of determining gas solubilities in crystalline material. (Edited author abstract) 15 refs.

**092131 NONLINEAR COMPUTATION OF AXISYMMETRIC SOLID RUBBER DEFORMATION.** This paper is devoted essentially to the detailed derivation of the element gradient vector and stiffness matrix for the nonlinear finite element analysis of axisymmetric rubber. The technique, which is based on the discrete sampling of the total potential energy of the deformed solid, is a natural extension of one employed previously in the nonlinear analysis of rubber membranes. However, in contrast with the thin membrane case exact incompressibility is avoided here and an extra energy term is added for the change of volume work. 14 refs.

**092132 NOTE ON ELASTIC ENERGY DENSITY FUNCTIONS FOR LARGELY DEFORMED COMPRESSIBLE RUBBER SOLIDS.** A successful finite element program for near-incompressible solids needs a good positive-definitive variational principle, and a mechanism to balance the physical and computational modeling requirements. This study has three points to make in this respect. One is to provide an elementary explicit proof to the theorem stating that an elastic energy density expression that is a function of the principal stretch ratios represents an isotropic material - a material with such a constitutive equation that the stress and strain matrices have colinear principal axes. Secondly, to show how the arithmetic-geometric-mean inequality theorem rationally leads to most of the elastic energy density functions in use for the large displacements analysis of nearly incompressible solids, and to possible new ones as well. Thirdly, to estimate, on a uniaxial stretching problem, the upper limit for the bulk modulus needed to reproduce the observed residual compressibility of rubberlike solids. 13 Refs.

**092134 ELASTIC STABILITY OF RUBBER PRODUCTS.** The problem of a sheet of Mooney-Rivlin type material, subject to general biaxial loading, is studied both analytically and by the finite element method. An energy approach to the problem is first presented. This problem represents the biaxial loading of rubber sheets or combined extension and inflation of rubber tubes, which are often used in experimental work for characterization of rubber materials. It is shown that the problem has multiple solutions for a certain domain of loading. The equilibrium state actually attained is dependent on the manner of quasistatic loading. Various stable solutions are obtained by the finite element method. 5 refs.

**092135 ORIGINS OF ENTANGLEMENT EFFECTS IN RUBBER ELASTICITY.** The effects of entanglements on a network chain with fixed ends are modeled as hoops through which the chain must pass. This model differs from the tube models which allow no 'chain leakage' from the tube and from the slip-link models which do not conserve monomer along the chain. The strain-dependent portion of the free energy as the chain ends are displaced is shown to arise from three factors: the entropy of the strained unentangled subchains spanning the hoops, the distortion of the hoops with strain, and the narrowing of the distribution of segments required to reach a hoop with increasing extension ratio. An analytical expression for the free energy of the chain can be derived that takes the  $M - 1$  hoops per chain to be of infinitesimal diameter thereby neglecting this second factor. (Edited author abstract) 13 refs.

Adolf, Douglas (Sandia Natl Lab, Albuquerque, NM, USA). *Macromolecules* v 21 n 1 Jan 1988 p 228-230.

**092136 EXCLUDED-VOLUME EFFECTS IN RUBBER ELASTICITY. 3. SEGMENT ORIENTATION.** The effect of excluded volume on segment orientation in rubber elasticity is studied by molecular dynamics simulation of model systems of freely jointed chains with a truncated Lennard-Jones repulsive potential acting between all atoms. In a single chain with fixed end-to-end distance  $L$  and periodic boundary conditions, it is found that excluded volume causes negative orientation for sufficiently small  $L$ . This effect has been observed previously for a tie molecule and suggests an analogy between the confining effect of the crystalline lamellae on the tie molecule and that of excluded volume on the chain with periodic boundary conditions. In a system of three chains, corresponding to the three-chain model of rubber elasticity, it is found that intrachain excluded-volume interactions alone cause a decrease in orientation in the tensile region, but inter- and intrachain interactions together cause an increase in orientation beyond the ideal chain case. (Edited author abstract) 28 refs.

**092137 RUBBER ELASTICITY AND FRACTURE.** Rubber is an amorphous elastomer of high entropy that is normally treated by statistical thermodynamics instead of molecular modeling. A pseudo-amorphous model is introduced that is useful in extending true stress-true strain uniaxial tensile results to other more complex states of stressing. While the statistical thermodynamic approach is still needed to deal with thermal aspects of rubber elasticity, the new approach represents a simpler, more accurate method of dealing with mechanical properties. Fracture of rubber follows a criterion of constant

engineering strain (or constant extension ratio) in the resultant principal stress direction which is consistent with the proposed model and the experimental results presented. (Author abstract). 9 Refs.

Shaw, M.C. (Arizona State Univ, Tempe, AZ, USA); Young, E. *J Eng Mater Technol Trans ASME* v 110 n 3 Jul 1988 p 258-265.

**092138 JUNCTION FLUCTUATIONS IN CONFINED CHAIN MODELS OF RUBBER ELASTICITY.** The junction fluctuations in a microneutral network of entangled chains are examined and compared to the assumptions made by the constrained junction theories. The entanglements acting on the microneutral network chains are pictured as hoops of infinitesimal diameter through which a chain must pass. Over a limited range of the uniaxial extension ratio, the calculated fluctuations qualitatively agree with the constrained junction theories. Quantitative agreement is improved by allowing the hoops to have finite size. However, junction fluctuations are seen to have little effect on the uniaxial force of the microneutral network. The force is dominated by the strain dependence of the chain entropy. This implies that agreement in the junction fluctuations is not sufficient to infer that the constrained junction theories correctly model the primary effects of entanglements on network chains. (Author abstract). 15 Refs.

## Electric Conductivity

**092139 ELECTRICAL CONDUCTIVITY AND ESR STUDIES OF CARBON-BLACK-LOADED NATURAL RUBBER.** The results of electrical conductivity and electron spin resonance (ESR) measurements on NR with four types of carbon black filler were reported. Two forms of space charge limited current (SCLC) were identified, indicative of different electron trap energies, depending on the type of carbon black filler. Such SCLC behavior, with steep trap-filling regions on the current-voltage curves, is indicative of trap-dominated transport in the polymer regions of carbon-black-NR composites. Discrete shallow traps are evident for two of the compositions; deep, exponentially distributed traps for two others. ESR spectra of the composites are very pronounced, with lineshape also depending on the type of carbon black used. Observed g-values are close to that of the free electron, and don't vary with carbon black type or temperature. Linewidths narrow and increase in intensity with increasing amounts of carbon black, with no detectable g-value shift. 12 refs.

## Evaluation

**092140 COMPARISON OF NATURAL RUBBER AND SYNTHETIC RUBBERS.** This technical note discusses the strengths and weaknesses of natural rubber in comparison with synthetic rubbers. The article outlines the important role played by compounding ingredients added to the base rubber; particularly influential are the vulcanizing system, type and level of filler and the chemical added to raise resistance to degradation. 5 refs.

Anon. *NR Technol* v 19 pt 1 1988 p 14-18.

## Extrusion

**092141 NONISOTHERMAL FLOW OF A GENERALIZED POWER-LAW FLUID IN CONVERGING SECTIONS FOR RUBBER EXTRUSION.** A method for predicting pressure drop and temperature distribution in convergent sections is proposed. The generalized power-law rheological equation of state is used. Only the shear component of the converging flow is considered in order to estimate its contribution to total flow in such sections. A finite-difference scheme was used to simulate

the flow. The method was applied to an ethylene-propylene terpolymer compound using different angles of approach for which the pressure drop and the extrudate temperature had been measured experimentally. Comparison with theoretically predicted data showed excellent agreement for small angles, while for large angles the inclusion of extensional effects was found to be necessary. (Edited author abstract) 32 refs.

**092143 MELT BLENDER FILLS THE GAP.** A high-performance, cold-feed extruder has been developed for the tire industry. By incorporating Sulzer AG's SSM-HV bolt-on melt blender into a standard cold-feed extruder, many of the drawbacks of such unmodified units may be overcome. The idea is not new - it has been used for many years in the chemical and plastics industries. What is new, however, is its use for the highly viscous melts found in rubber processing. The melt blender is suitable for applications where a high throughput, close tolerances and a homogeneous mix are needed. 1 ref.

**Fillers** See Also CARBON FIBER—Physical Properties; RUBBER PRODUCTS—Modification; RUBBER TESTING—Tensile Tests; RUBBER TESTING—Wear.

**092145 MAGNESIUM SILICATE FILLER IN RUBBER TREAD COMPOUNDS.** Carbon blacks keep their dominant role among the rubber fillers and account for about 60% of total filler consumption. Since the energy crisis and due to its negative effect on carbon black manufacturing cost, greater interest has been put into the search for alternative fillers and particularly in cheaper inorganic materials, either natural or synthetic, that after suitable treatments can reach reinforcement levels very close to those of carbon black. Along this line, in the present work the mineral, sepiolite, a magnesium silicate with microfibrillar morphology, as a filler for rubber compounds is studied. The properties of two conventional compounds for passenger and truck tire treads are compared with similar formulations in which sepiolite is substituted for part (30% maximum) of the carbon black. 6 refs.

Gonzalez Henandez, Luis (Inst de Plasticos y Caucho, Madrid, Spain); Ma Ibarra Rueda, Luis; Chamorro Anton, Celia. *Rubber Chem Technol* v 60 n 4 Sep-Oct 1987 p 606-617.

**092146 TRANSIENT ELECTROMECHANICAL BEHAVIOR OF CARBON-BLACK-FILLED RUBBER.** This work shows the sensitivity and uniqueness of conductivity and dielectric constant transient response to compressional stress for natural rubber filled with specific types of carbon black. The strong correlation between conductivity and capacitance (both steady-state magnitudes and transients) is attributed to the polymer itself. A qualitative model for these effects is based on changes of conductive and resistive microelements due to fracture of the carbon black matrix. 16 refs.

Parris, Donald R. (Virginia Polytechnic Inst & State Univ, Blacksburg, VA, USA); Burton, Larry C.; Siswanto, Muliawati G. *Rubber Chem Technol* v 60 n 4 Sep-Oct 1987 p 705-716.

**092147 EFFECT OF INORGANIC PEROXIDE ON NATURAL RUBBER-CARBON BLACK SYSTEM.** The chemical used for enhancing the polymer-filler interaction prior to or during mixing results in improved green strength and thus yield vulcanizates with better physical properties. In this paper the authors report the results of studies on the effect of inorganic peroxide on carbon black-rubber interaction during mixing. Both hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) and solid zinc peroxide were used in HAF-black (N330) and GPF-black (N660) in natural rubber systems. The effect of peroxide on steel cord-rubber adhesion has also been studied. 8 refs.

Chakraborty, S.K. (JK Industries Ltd, Udaipur, India); Mukherjee, D.P. *J Appl Polym Sci* v 34 n 7 Nov 20 1987 p 2623-2629.

**092148 SEPIOLITE - A NEW INORGANIC ACTIVE FILLER FOR THE RUBBER INDUSTRY.** The use of sepiolite, a natural silicate, as a filler for rubber compounds is studied. Due to its marked adsorptive nature the sepiolite delays the vulcanization, and therefore the addition of an activator is needed. Tri-ethanolamine and di-ethyleneglycol, added during the mixing in the roll mill, have been studied for this purpose. Normal or even higher cure rates are obtained. The use of a silane coupling agent improves markedly the properties of the vulcanizates filled with sepiolite, which reach the level normally obtained with a fine particle precipitated silica. (Edited author abstract) 5 refs.

Gonzalez, H.L.; Ibarra, R.L.; Royo, M.J.; Rodriguez, D.A.; Chamorro, A.C. *Kautsch Gummi Kunstst* v 40 n 11 Nov 1987 p 1053-1057.

**092149 KOHLEN ALS FUELLSTOFFE FUER KAUTSCHUKE - VERSUCHE ZUR BEEINFLUSSUNG DER EIGENSCHAFTEN.** [Coal as Filler for Rubber - Experiments to Change Properties]. The properties of finely ground coal as filler for technical rubbers were investigated by way of two rubbers as examples and compared with the properties of thermal black. Comminution without access of oxygen and addition of stearates, resins, and fatty alcohols do not change the properties considerably. Because coal has a substantially smaller density than carbon black, the parts of filler in rubber were varied, and a comparison between coal and thermal black on the basis of equal parts by volume was performed. (Edited author abstract) In German. 3 refs.

Baumann, H.; Ambroz, F.-J.; Klein, J.; Juentgen, H. *Kautsch Gummi Kunstst* v 41 n 2 Feb 1988 p 154-156.

**092150 PRODUCT MODIFICATIONS IMPORTANT IN FILLERS.** Carbon black usage by the U.S. rubber industry is over double that of the inorganic fillers. About 90 percent of non-carbon fillers are clays, calcium carbonates, silicas, and silicates. More than 100 grades of these products are available, many developed for specific product applications. Filler characteristics such as the size and shape of particles and aggregates, the chemical nature and extent of surface dispersibility, and the tendency to

agglomerate and form secondary filler networks, determine rubber properties. A variety of surface treatments and 'coupling' agents have been developed for the inorganic fillers, which give better dispersion, increased surface activity, and improved rubber properties. 5 refs.

Dannenberg, Eli M. *Elastomerics* v 119 n 12 Dec 1987 p 22-25.

**092151 OPTIMUM LOADING OF CARBON BLACK IN RUBBER BY MONSANTO OSCILLATING DISC RHEOMETER.** Evaluation of different carbon blacks by the measurements of rubber properties is an accepted industrial practice. Very often carbon blacks are compared at the same weight percent loading. The present work suggests that carbon blacks should be compared at the 'optimum loading' which is different for different blacks. A procedure for determination of optimum loading from Monsanto rheometer curves is suggested. The method is based on the different hydrodynamic effect of carbon black aggregate reinforcement on viscosity (uncured stock) and modulus (cured stock). A parameter  $L$ , defined as  $L = \eta_r - Mr$  ( $\eta_r$  = relative viscosity,  $Mr$  = relative modulus), is determined from the rheometer curves at different carbon black concentrations. As the concentration exceeds the 'optimum loading',  $L$  rises sharply showing a preponderance of undispersed carbon black agglomerates. This value has been determined for a number of carbon blacks and has been correlated with carbon black parameters and rubber properties. 15 refs.

Sircar, Anil K. (J.M. Huber Corp). *Rubber World* v 197 n 2 Nov 1987 p 30-35, 44.

**092152 PROCESSING EASE AND RUBBER-CARBON BLACK INTERACTION.** Two samples of poly(ethyl acrylate) rubber, different in their mill processability and their manner of accepting carbon black were examined. This is a case history of how the authors differentiated rheological behavior of gum elastomers and how the authors characterized the rubber-carbon black interaction in the compound. The dynamic mechanical properties were measured over the temperature range of interest. This information was used to interpret the difference in mill processability. Several carbon blacks in different particle size and structure were compounded with these samples. The effect of the different carbon blacks on these elastomers was examined with tensile stress-strain measurements. At least a part of the differences in behavior could be interpreted as the differences in the interaction between rubber and carbon black. 24 refs.

**092153 FILLER REINFORCEMENT IN RUBBER.** A general introduction of reinforcement of rubbers by particulate fillers has been discussed, with major emphasis on the common factors which affect reinforcement levels of fillers in rubbers. Mechanism of reinforcement, some of which are not clearly discernible, and the role of hysteresis in reinforcement have not been discussed. A discussion is also presented of the ability of any filler to reinforce rubber, which is determined by three main characteristics. These are: particle size, structure or state of aggregation of filler particles, and the physical and chemical nature of the filler surface. 20 refs.

Ogunniyi, David S. (Univ of Ilorin, Nigeria). *Elastomerics* v 120 n 8 Aug 1988 p 24-27.

## Fire Resistance

**092154 EFFECTS OF BROMINATED FLAME RETARDANTS AND CROSSLINKING AGENTS ON THE FLAME RETARDANCY OF RUBBERS.** Tetra-bromo-p-cresol (TBPC), pentabromophenol (PBP), and their allyl ether derivatives - tetra-bromo-p-cresol allyl ether (TBPC-AE) and pentabromophenol allyl ether (PBP-AE) - were used in the study of flame retardancy of ethylene-vinyl acetate (EVA) copolymer and styrene-butadiene rubber (SBR), which were cured by dicumyl peroxide (DCP) and sulfur, respectively. The depen-

dence of the flammability of crosslinking polymers on the polymer matrix, its additives, and the degree of crosslinking was investigated. The empirical equations of flame retardancy were established for these rubbers and compared with the measured values. It was found that the oxygen index of SBR-S system was in accordance with the empirical equations, while the EVA-DCP system, affected by the decomposed residue of DCP, showed a slight deviation. (Edited author abstract) 17 refs.

## Fracture

**092155 J-INTEGRAL AND CRACK OPENING DISPLACEMENT AS CRACK INITIATION CRITERIA IN NATURAL RUBBER IN PURE SHEAR AND TENSILE SPECIMENS.** The purpose of this study was to determine, based on the concepts of J-integral and crack opening displacement, the failure criterion of carbon-black-filled NR in pure-shear specimens and to compare the results with those in SEN specimens and with the tearing energy. 9 refs.

Lee, R.F. (Univ of Massachusetts, Amherst, MA, USA); Donovan, J.A. *Rubber Chem Technol* v 60 n 4 Sep-Oct 1987 p 674-688.

## Friction

**092156 IMPORTANCE OF STRUCTURAL INHOMOGENEITY IN THE FAILURE OF RUBBER SURFACES IN FRICTION AGAINST METALS.** The influence of the structural inhomogeneity of filled elastomers on their failure in friction against metals is indicated. Attention is concentrated on the variable capacity of the rubber for deformation under the physical and mechanical interactions at the solid filler/rubber matrix interface under sign-alternating loads. Microinhomogeneous deformation of filled elastomers is attained by replacing homogeneously deformed elastomers with equivalents having a certain effective length. The thickness of the layer around the filler is calculated and experiments are performed to determine it. (Edited author abstract) 17 refs.

Polyakov, P.V.; Antsupov, Yu. A. *Sov Mach Sci* n 6 1987 p 34-37.

**092157 EFFECT OF HIGH-FREQUENCY GLOW-DISCHARGE TREATMENT ON RUBBER PROPERTIES.** The change in the physical and mechanical indices and friction coefficient of rubbers subjected to a high-frequency glow discharge with the use of various gas media (argon, oxygen, Freon) is described. It is shown that such treatment improves the friction properties of rubbers under conditions of low-speed axial friction. (Author abstract) 3 refs.

## Grafting

**092158 STUDIES ON GRAFT COPOLYMERIZATION OF METHYL METHACRYLATE IN NATURAL RUBBER LATEX INDUCED BY GAMMA RADIATION.** Methyl methacrylate graft natural rubber was prepared by initiating the polymerization of methyl methacrylate in natural rubber field latex using  $\gamma$  rays. The combined effect of radiation and chemical initiation was also studied. Properties of these graft rubbers were compared with those prepared using only redox catalysts. (Author abstract) 5 refs.

**092159 TOOLS FOR INJECTION MOULDING OF RUBBER.** This report describes the present state of technology in injection molding tools for rubber processing. Topics covered are the design and construction of tools, including computer-aided methods, and different injection molding systems, with particular emphasis on cold channel tools. The requirements for tools used in automated injection molding of rubber are described with the help of practical examples. (Edited author abstract)

Hofmann, W. *Kunstst Ger Plast* v 77 n 12 Dec 1987 p 3-12.

## Isomerization

**092160 COMPARISON OF METHODS OF CALCULATION OF  $^{13}\text{C}$ -NMR CHEMICAL SHIFTS OF DIENE POLYMERS WITH APPLICATIONS TO ISOMERIZED NATURAL RUBBER.** Natural rubber was isomerized by two methods that involved either dehydrobromination of hydrobrominated natural rubber or heating natural rubber with butadiene sulfone. The  $^{13}\text{C}$ -NMR spectra of the methylene region of isomerized natural rubber was interpreted in terms of dyad arrangements for which assignments were made by calculating chemical shifts according to three different published methods. Contrary to literature reports, it was found that the sulphur dioxide catalyzed isomerization of natural rubber was accompanied by a significant amount of double bond migration; a possible reaction scheme was proposed. (Edited author abstract) 35 refs.

**Latex** See Also MICROSTRIP DEVICES.

**092161 PRODUCTION OF ACID FROM COCOA SWEATINGS AND ITS USE FOR COAGULATION OF NATURAL RUBBER LATEX.** Cocoa sweating drain off during the fermentation of cocoa beans and are normally a waste. These sweatings were converted to ethanol and then to a mixture of acids by successive fermentation by yeast and bacteria. Of the acid formed, 25 to 50% was non-volatile and was unidentified. The acid was used to coagulate rubber latex to form RSS No. 1 smoked sheet rubber which was similar to rubber from latex coagulated with formic acid. The advantages are that many estates grow both cocoa and rubber, lower production costs of rubber, and an environmental benefit, cocoa sweatings normally being a pollutant. (Author abstract) 11 refs.

Sarath-Kumara, Subaddarage J. (Ceylon Inst of Scientific & Industrial Research, Colombo, Sri Lanka); Jansz, Errol R.; Tillekeratne, L.M. Kirithi; Wickremasinghe, L. Kirithi G.; Mendis, Leslie P. *J Chem Technol Biotechnol* v 39 n 1 1987 p 11-18.

**092162 STUDY OF THE MECHANISM OF ACTION OF AROMATIC THIOLS ON CAROTENOID PIGMENTS.** Aromatic thiols are used widely to bleach carotenoid plant pigments present in natural rubber latex in trace quantities, in the manufacture of white latex crepe rubber. If this is not done these pigments impart a yellow color to the crepe, thereby lowering its grade. The bleaching reaction between carotenoid pigments and aromatic thiols is known to occur in the presence of at least diffuse daylight. In this mechanistic study it was observed that the aromatic thiols have no action on unoxidized carotene. (Edited author abstract) 10 refs.

**092163 FURANIZED RUBBER STUDIED BY NMR SPECTROSCOPY.** The double bonds of natural rubber latex (stabilized by a nonionic surfactant) were reacted with an approximately equimolar amount of

performic acid at room temperature with a limited amount of formic acid present. Product analysis by  $^1\text{H}$ -NMR during the course of the reaction showed that 69-90% epoxidation occurred before the advent of ring opening and ring expansion to produce furanized rubber; hence the rate of epoxidation was greater than the rate of furanization. By  $^1\text{H}$ - and  $^{13}\text{C}$ -NMR, it was found that the furanized rubber probably consisted of tetrahydrofuran rings linked together by C-C bonds at positions adjacent to the hetero atom and contained a terminal hydroxy group. (Edited author abstract) 28 refs.

Perera, M.C.S. (Australian Natl Univ, Canberra, Aust); Elix, J.A.; Bradbury, J.H. *J Polym Sci Part A* v 26 n 2 Feb 1988 p 637-651.

**092164 DRYING EFFECTS IN NATURAL RUBBER LATEX FILMS.** Drying rates of natural rubber latex films have been studied using control of drying conditions such as temperature and humidity. The effect of compound modification on drying has also been assessed. Improved drying rates can be obtained by physical variation of drying conditions: such improvements are likely to be specific to a particular oven and how it is loaded. The overall drying rate may be usefully increased by certain compound modifications such as prevulcanization or the addition of low levels of hard polymers, particularly polystyrene, which has little effect on physical properties. (Author abstract) 8 refs.

Gazeley, K.F.; Swinyard, P.E. *NR Technol* v 18 Pt 4 1987 p 81-87.

**092165 EFFECT OF METALLIC CATIONS ON THE ELECTROPHORETIC PROPERTIES OF A PRETREATED HEVEA LATEX.** High-ammonia latex concentrate prepared from doubly-centrifuged field Hevea latex was exhaustively dialysed to remove any residual water-soluble non-rubber constituents. The electrophoretic mobilities of the dialysed latex in the presence of various metallic cations were investigated as a function of electrolyte concentration. It is believed that strong adsorption of hydrolysed species from the metallic ions was responsible for reversing the charge of the originally negative latex particles. The number of cation binding sites on the latex particle surface and the chemical free energies of cation adsorption were calculated. It was found that the interaction of the latex particle with the hydrolysable metallic cations was much more stronger than that with the simple divalent cations and that this interaction was comparable to that of biological surfaces. (Edited author abstract) 28 refs.

## Manufacture

**092166 DER WIRTSCHAFTLICHE MISCHBETRIEB DES GUMMIFORMTEILHERSTELLERS.** [Economic Mixing Plant for the Manufacture of Molded Rubber Parts]. The main requirements of an economic mixing plant are shown in detail from a diagram of the equipment, the heart of which is the rubber mixer. Possibilities of improving quality and increasing output are shown in case a new investment is to be made and the best mixing system can be chosen. In addition, possibilities of optimizing existing machines are shown for customers with their own mixing plant. Improvements in quality stability are dealt with. The mixing cycle can be optimally controlled and regulated and the entire production better supervised by using micro-computer systems. (Edited author abstract) In German. 2 refs.

Schmid, H.-M. *Kautsch Gummi Kunstst* v 40 n 9 Sep 1987 p 820-825.

**092167 NATURKAUTSCHUK IM JAHR 2000.** [Natural Rubber in the Year 2000]. On basis of statistical evaluations forecasts are presented for a worldwide

increase of the NR production reaching 7 to 8.8 mill tons/a by means of a complex of scientific and socio-economic measures, which would mean a doubling of NR production during the next 13 years. The prognosis considers an important increase in the yield per hectare, an enlargement of the planting area, and an economically viable balance of the total rubber consumption of 40% NR, 40% SR, and 20% of speciality rubbers. Finally, an energy balance is discussed from the economic aspects. (Edited author abstract) In German.

Heinsch, K.F. *Kautsch Gummi Kunstst* v 41 n 3 Mar 1988 p 233-235.

**092168 RUBBER-SOFT - EIN PROGRAMMSYSTEM FUER ELASTOMERVERARBEITER.** [RUBBER-SOFT - A Program for Elastomer Molders]. The program RUBBER-SOFT calculates the process parameters, which are important for producing elastomer moldings (pressure drop, material temperature, scorch-index and cure rate). The program also does calculations for mold design and optimizing process conditions. The software uses modules for the preparation of material data (RUBBER-D), for calculation of pressure drop (RUBBER-P) and for calculation of vulcanization (RUBBER-V). Ease of handling and short calculation times are characteristic of the program. Different examples show typical applications of the program. (Edited author abstract). 4 Refs. In German.

## Marketing

**092169 ORIENTATION DU MARCHÉ DU CAOUTCHOUC NATUREL.** [Natural Rubber Market Trends]. The world consumption of natural rubber has increased by 26% over the last ten years, from 3,500,000 tons in 1976 to 4,425,000 tons in 1986 (the present increase being more than 100,000 tons per year). At the same time, the consumption of synthetic rubber has increased from 8,100,000 tons to 9,160,000 tons, i.e., an increase of 13%. The share of natural rubber has increased from 30.7% to 32.6% of the total rubber consumption and this percentage has remained stable for about 5 years. The three main producers (Malaya, Indonesia and Thailand) have modified production and other countries, more recent cultivators of hevea, such as Liberia, the Ivory Coast and Cameroon now produce specified rubbers. (Edited author abstract) In French. 2 refs.

## Mechanical Properties See Also ELASTOMERS —Mechanical Properties; POLYMERS—Fillers.

**092170 STUDY OF NATURAL RUBBER IN COMPRESSION.** The non-linear kinetic-statistical theory of rubber elasticity is applied to the case of natural rubber blocks loaded in compression through steel platens bonded to the rubber. The rubber elasticity equations are modified for the bonded ends conditions by a theoretically derived shape parameter function which enhances the value of the shear modulus term. These equations form the basis for analyzing experimental data for compression tests on rubber specimens bonded to steel platens. From this analysis the applicability of the modified rubber elasticity equations are then assessed by comparisons between test results and theory. (Author abstract) 11 refs.

**092171 GENERALIZED CRITERION FOR RUBBER TOUGHENING: THE CRITICAL MATRIX LIGAMENT THICKNESS.** The thickness of matrix ligament is shown to be the single parameter determining whether a polymer/rubber blend will be tough or brittle.

The matrix ligament is defined as the region of the matrix between two neighboring rubber particles. Specifically, the ligament thickness is the surface-to-surface interparticle distance. When the average ligament thickness is smaller than a critical value, a blend will be tough; when greater, it will be brittle. In other words, a sharp brittle-tough transition occurs at the critical ligament thickness. This critical parameter is independent of rubber volume fraction and particle size, and is characteristic of the matrix for a given mode, temperature and rate of deformation. What is important is the matrix ligament, not rubber particles. The single matrix parameter explains the effects of phase morphology, rubber volume fraction, particle size, particle-size polydispersity, and particle flocculation on toughness. (Author abstract) 14 refs.

Wu, Souheng (DuPont, Wilmington, DE, USA). *J Appl Polym Sci* v 35 n 2 Feb 5 1988 p 549-561.

**092172 DESIGN BASICS: STRESS-STRAIN RELATIONSHIPS.** Designers of rubber articles need to be aware of the basic stress-strain relationships in rubber. Likewise, rubber technologists need to be aware of the problems that the product designer is trying to overcome. As the part becomes more complex, this problem is magnified. As a rule, the stress-strain properties measured by the rubber technologist will be orders of magnitude greater than the product designer is concerned with. Likewise, typical rubber properties are measured in tension while most rubber articles are used in compression. Being able to relate these two points of view is critical to being able to correctly identify and specify properties in a material to be used.

Menough, Jon (R.M. Engineered Products, North Charleston, SC, USA). *Rubber World* v 197 n 2 Nov 1987 p 8-9.

**092173 NATURAL RUBBER IN ENGINEERING.** The purpose of this paper has been to draw the attention of engineers and designers to the enormous potential for using natural rubber as an engineering material. Its versatility awaits further exploitation by the innovator. Extensive data are available to assist in the designing of natural rubber components completely reliable in function. Some of the topics covered include vulcanization, compounding temperature effect on properties, weathering resistance, swelling phenomena, and recent development in rubber utilization. 36 refs.

Lindley, P.B.; Leaver, A.D.W. *NR Background* n 2 9p.

**092174 DESIGN BASICS - RUBBER IN SHEAR.** In previous papers two basic methods of applying load to rubber articles were reviewed - tension and compression. In this paper applying load through shear is reviewed. In moving from tension and compression to shear, the understanding of how a rubber product reacts to the forces applied becomes significantly more complex. As previously noted, shear is a combination of both tensile and compressive forces acting at right angles to each other. However, having a basic feel for the effects of shear is very important in having a basic understanding of rubber and the products made from it. While we often consider isolated forces and their effect on a given product, there are very few products that are, in the real world, acted upon by solely one force. And often, that additional force will have a dramatic effect on the performance and life of the product.

Menough, Jon (Rubber World, Akron, OH, USA). *Rubber World* v 198 n 2 May 1988 p 12-13.

**092175 MODELLING AND ANALYSIS OF RUBBERLIKE MATERIALS.** A numerical scheme for strictly and nearly incompressible rubberlike materials is described. A Total Lagrange description is adopted to describe the large deformations that occur. A separate interpolation for the displacements and the pressures is used to model the (near) incompressibility. The employed constitutive model can be classified as hyperelastic with the strain energy function being composed of a deviatoric and a volumetric contribution. Thus, the volumetric deformations can be controlled in a physically realistic

manner, which is important since experimental evidence indicates that, although the ratio of bulk modulus over shear modulus is very large for rubbers, volumetric strains cannot be neglected. The second part of the paper is devoted to a number of practical examples. (Edited author abstract). 25 Refs.

## Microstructure

**092176 POLYMERSTRUKTUR UND REVERSION.** [Polymer Structure and Reversion]. Reversion phenomena are caused by subsidiary reactions of sulphur. The course of sulphur reaction, however, is to no small extent a matter of polymer structure. Correlations between the microstructure and reversion are shown using a series of models based on butadiene, styrene and isoprene. By number and type of double bonds and side groups the appearance of the rheometer curves can be enhanced. An attempt to give a theoretical interpretation is made. Ways of overcoming reversion problems by tailor made polymer structures are offered. (Edited author abstract) 12 refs. In German.

## Mixing See Also RUBBER MACHINERY—Extruders; RUBBER MACHINERY—Mixers.

**092177 INTERNAL MIXING: A PRACTICAL INVESTIGATION OF THE INFLUENCE OF INTERMESHING ROTOR CONFIGURATION AND OPERATING VARIABLES ON MIXING CHARACTERISTICS AND FLOW DYNAMICS.** This paper deals with the measurement and interpretation of pressures and temperatures produced by the mixing of a rubber compound in the chamber of an internal mixer equipped with interlocking rotors. Pressure transducers and infrared/fiber optic temperature sensors were sited flush with the inner surface of the mixing chamber of a Francis Shaw KO Intermix of 2 L chamber volume. The variation of pressure with transducer position in the chamber wall and with rotor position was measured for selected fill factors and rotor speeds at 'equilibrium' conditions (quasi-static power requirement for the mixer) and at intervals during a complete mixing cycle. Two rotor designs were studied. Interpretation of the results was carried out with reference to biconical rotor rheometer measurements on the mixed rubber compounds and by reference to four regimes of viscoelastic behavior identified for two-roll mill mixing. (Edited author abstract) 26 refs.

Frakley, P.K. (Loughborough Univ of Technology, Engl); Patel, S.R. *Polym Eng Sci* v 27 n 18 Mid-Oct 1987 p 1358-1370.

**092178 BUEMATIC - MIKROPROZESSORSYSTEM FUER EINE KAUSCHUKMISCHLINIE.** [BUEMATIC - Microprocessor System for a Rubber Mixing Line]. In the rubber industry with consumers' quality expectations constantly increasing, a general automatic control of raw material dosing, mixing and, in case necessary, re-treatment is required in any production line. Besides the strategy of the control goals achievable of the automatic control system itself shall be explained. A description is given of the hardware, especial characteristics, the range of action, efficiency and the advantages of applying the BUEMATIC. The system presented is distinguished by safe and user friendly operation as well as transparent presentation and documentation of its process. (Edited author abstract) In German.

Goehler, D. v 41 n 2 Feb 1988 p 160-163.

**092179 IMPROVED DISPERSIVE MIXING THROUGH REDUCTION IN FLOW FIELD VORTICITY.** Dispersive mixing is most efficiently accomplished with pure straining flow. Vorticity in the flow field

inhibits this extending action; accordingly, the presence of shearing flow will decrease the overall effectiveness of dispersive mixing processes. A method to reduce the vorticity by inducing lubricated flow through development of a nonuniform distribution of the components of a polymer blend is described. (Author abstract) 24 refs.

Roland, C.M. (US Naval Research Lab, Washington, DC, USA); Nguyen, M. *J Appl Polym Sci* v 35 n 8 Jun 1988 p 2141-2154.

**092180 ANALYSIS OF APPEARANCE MECHANISM OF FINE PARTICLES IN INITIAL PERIOD OF NR MIXING.** Various solid behaviors of NR in an initial period of mixing and their properties as upgraded by control are described. A block of NR charged into a mixer was initially broken under the breaking condition in tensile strength and then transformed into many fine particles due to nonuniform elasticity in melt fracture occurring in NR film. These behaviors influenced the reduction rate of Mooney viscosity and the effective dispersion of carbon black mixed into the NR. (Author abstract) 6 refs. In Japanese.

Hashizume, Shinji. *R&D Res Dev Kobe Steel Ltd* v 38 n 2 Apr 1988 p 50-53.

**092181 COMPUTER INTEGRATED MANUFACTURING APPLIED TO AN INTERNAL MIXER.** The demand for tire quality is increasing. The uniformity of tire components can be improved by a staged approach to mixed rubber quality. The three major players - equipment, raw materials and controls - all have roles to play in an improvement program. A planned approach should include improvements in: process visibility, process consistency, and process control. A system is needed which includes: a data base that makes information available at any time, anywhere; an effective interface between the operator and the process; easily modified displays and reports for MIS and SPC; flexibility to change when the requirements change; and controls which can expand with the process.

Wolf, Craig A. (Measurex Corp). *Rubber World* v 198 n 3 Jun 1988 p 18-20.

**092182 COMPUTER PROGRAMS FOR COMPOUND DEVELOPMENT, MILLROOM RECORD SYSTEMS.** Chase Elastomer Corporation wrote its own software to manage its own rubber formulations, inventory, and production control. The software is named Millroom Record System, or MRS, developed to run on IBM-PC or compatible personal computers. Unlike earlier computer systems, the MRS software was designed for ease of use, even by those not familiar with computers. The operator is guided through each step with a prompt, or set of instructions or questions whereby all that is required is to supply the requested data or information.

Chase, Tom (Chase Technologies Inc). *Rubber World* v 198 n 3 Jun 1988 p 21-23, 25.

## Moisture Determination

**092183 APPLICATION OF MICROSTRIP SENSORS FOR DETERMINATION OF MOISTURE CONTENT IN HEVEA RUBBER LATEX.** The application of microstrip sensors for determination of moisture content or total solid content (t.s.c) in hevea rubber content is described. The sensors with characteristic impedances 93- $\Omega$  (on polyguide substrate), 50- $\Omega$  (on polyguide) and 50- $\Omega$  (on RT-Duroid) have been tested. The accuracy and reproducibility of 93- $\Omega$  sensor are at a level of 0.5 percent (compared with Standard Gravimetric Method) and 0.7 percent moisture content (wet basis) respectively. This performance is better than the previous technique using twin-horn antennas. With this accuracy, rapidity, ease of operation and compactness, this method has been found to be satisfactory for use in the field where t.s.c. determination is a prime factor in payment to the rubber tapper. (Author abstract). 10 Refs.

**092185 INJECTION MOULDING MACHINES FOR RUBBER PROCESSING.** A discussion is presented of the Oro series of molding machines. Criteria for microprocessor selection are presented. A four-nozzle injection molding machine for elastomer processing is described. Automatic demoulding is outlined. In English and German.

Bernhardt, I. *Kunstst Ger Plast* v 78 n 3 Mar 1988 p 11-12.

## Molecular Structure

**092186 VIBRATIONAL SPECTROSCOPIC ANALYSIS OF THE STRUCTURE OF NATURAL RUBBER.** The authors have obtained a series of well-defined raw rubber samples of both gel and sol fractions by well-established separation techniques. In this study, the authors have used infrared spectroscopy to better understand the structural aspects of the two fractions by identifying and interpreting different infrared spectroscopic features found in each fraction. Main emphasis was given to assess the number, magnitude, and the functional groups associated with hydrogen bonding. These data are useful in the characterization of intermolecular interactions and their effects on raw-rubber mechanical properties. 19 refs.

**Molecular Weight** See Also POLYPROPYLENE—Freezing.

**092187 VARIATION IN THE MOLECULAR WEIGHT DISTRIBUTION OF RUBBER FROM CULTIVATED GUAYULE.** The molecular weight (MW) and the molecular weight distribution (MWD) of natural rubber (NR) are directly related to rubber quality. Guayule, *Plathium argentatum* Gray, can synthesize high MW rubber similar to Hevea and is actively being developed as a new source of NR for the arid regions of the world especially in the United States. The purpose of this study was to examine the MW and MWD of guayule rubber obtained from cultivated plants to see whether agronomic management affects rubber quality. Analyses were made on different varieties of guayule grown under different irrigation regimes and harvested at different times of the year. In addition, plants treated with bioregulators, shown previously by others to increase rubber production, were tested for their effects on rubber MW and MWD. 15 refs.

## Oxidation

**092188 ALTERNATING CURRENT VOLTAMMETRY AS A MEANS OF INVESTIGATING TRANSFER OF METALS IN ISOPRENE RUBBER OXIDIZED ON ALLOYS.** The transport of metals in isoprene rubber oxidized in the presence of alloys (brass and Kovar) has been investigated by means of ac voltammetry. Contact oxidation occurring in the volume of the rubber is accompanied simultaneously by the accumulation of catalytically active alloy components in

the rubber. Oxidation of the SKI-3 on a metal substrate is accompanied by degradation and by crosslinking of the macromolecules. The degradation appears as a reduction in the specific viscosity of the SKI-3 (Polyisoprene Rubber) solution at the stage of the induction period in the oxidation process. The rate of degradation of the films depends on the nature of the substrate. For instance, SKI-3, films on a copper substrate degrade more rapidly than on an aluminum one. (Edited author abstract) 6 refs.

Yeliseyeva, I.M. (Gomelsk State Univ, USSR); Sviridenko, V.G.; Lin, D.G. *Polym Sci USSR* v 28 n 7 Jul 1987 p 1731-1733.

## Ozone Resistance

**092189 ZUR OZONBESTÄNDIGKEIT VON CM-VULKANISATEN.** [Ozone Resistance of CM-Vulcanizates]. The resistance of CM-vulcanizates against moist ozone attack was studied. Thiadiazole-cured CM-vulcanizates turned out to be resistant, whilst peroxide-cured CM-vulcanizates require adequate compounding to guarantee resistance under extreme conditions. Among other things the antioxidant AFS, a product proved for CR-compounds, is suitable for this purpose. (Author abstract) 8 refs. In German.

## Phase Transitions

**092190 ON THE DIFFERENCES BETWEEN THE GLASS TRANSITION TEMPERATURE OF NATURAL RUBBER AND ITS SYNTHETIC ANALOGUES AS MEASURED BY D.S.C. ANALYSIS.** The glass transition temperature of natural rubber and high cis synthetic polyisoprenes have been compared by careful d.s.c (differential scanning calorimetry) analysis. Natural rubber is found to have a glass transition temperature some 0.7-0.9 K lower than the synthetic analogues. The small difference is shown to be the result of plasticization by non-rubber impurities in the natural material, and not due to presence of trace 3,4-units in the synthetic analogues. (Author abstract) 6 refs.

Burfield, David R. (Univ of Malaya, Kuala Lumpur, Malays). *Polym Commun (Guildford Engl)* v 29 n 1 Jan 1988 p 19-20.

**Physical Properties** See Also THERMOPLASTICS—Additives.

**092191 COMPARATIVE PROPERTIES OF NATURAL RUBBER AND SYNTHETIC ISOPRENE RUBBERS.** The properties of engineering vulcanizates of isoprene rubbers (IRs) and natural rubber have been compared using compounds reinforced with N550 (FEF) black, and containing various vulcanizing systems. In most physical properties synthetic IRs were found to be similar to natural rubber, but differences occurred at high temperatures and in nonrelaxing fatigue resistance. Here natural rubber (100% cis-1,4 IR) exhibited superior strength to 96-98% cis-1,4 IRs, which in turn were superior to 92-94% cis-1,4 IRs. The low compression set and creep of synthetic IRs may be beneficial in some applications, but these properties are offset by their inferior fatigue life and hot strength compared to natural rubber. (Author abstract) 8 refs.

Elliott, D.J. *NR Technol* v 18 Pt 4 1987 p 69-74.

**092192 DETERMINATION OF SEQUENCE DISTRIBUTION OF STYRENE UNITS IN CURED SBR.** The sequence distribution of styrene units is known to be one of the most important structural factors governing the physical properties of cured styrene-butadiene rubber (SBR). The authors have proposed a new method for the analysis of the sequence distribution of styrene and 1,2-butadiene units in SBR by a combination of ozonolysis

and high-resolution GPC measurements. This ozonolysis-GPC method provides quantitative information about the distribution of styrene units for short to long styrene sequences in random, partially blocked, and triblock copolymers; and also about the arrangement and tacticity of styrene and 1,2 units. The ozonolysis-GPC method was applied to the analysis of the sequence distribution of styrene units in cured SBR. 7 refs.

**092193 SURFACE MODIFICATION OF NATURAL RUBBER LACES.** Epoxidation has been applied to modify the surface of natural rubber laces. When very thin laces of fractionated bleached rubber are used, about 6% of the double bonds could be modified. Using <sup>1</sup>H nuclear magnetic resonance (NMR) and infrared (IR) analysis the best condition for the reaction was worked out. Both <sup>13</sup>C NMR and differential scanning calorimetry (DSC) results indicate that the 6% epoxide groups are placed in a predominantly block manner. Modification in yellow fraction rubber however gives lower epoxy contents. Increase in glass transition temperature by epoxidation results in more damping and better abrasion resistance. The resultant polymer acts very similarly to a 90/10 natural rubber/50% epoxidized natural rubber (NR/ENR-50) blend. (Author abstract) 20 refs.

**092194 LABORATORY METHOD OF ASSESSMENT OF MOULD RELEASE OF CURED RUBBER USING A TMS RHEOMETER.** Mold release in rubber processing is a frequently encountered problem. Difficulties in quantitatively measuring the low levels of adhesion involved have hindered research work on the topic. This paper describes the use of the TMS rheometer to obtain a measure of mold release. A blank of uncured rubber is molded around a stationary bioconical rotor, representing the mold surface. After curing the rubber in situ, an electric motor starts the rotor and the peak stress at its surface as the rubber breaks free is taken as the 'mold sticking index'. The preconditioning of the rotor necessary for obtaining reproducible results is described. (Edited author abstract) 5 refs.

**092195 EIN KONZEPT ZUR DIREKTVERARBEITUNG VON PULVERKAUTSCHUK AUF SPRITZGIESSMASCHINEN.** [Conception for Direct Processing of Powder Rubber on Injection Molding Machines]. This report summarizes theoretical and practical results of research activities. Experimental studies for the description of plastification behavior of an injection molding plastification unit were made. Especially the resulting mixing homogeneity was investigated dependent on variation of screw geometry and processing parameters. The best results were obtained by using a screw with a short and strong compression and shearing and mixing elements in the metering zone, which are necessary for dispersion and distribution of carbon black. **092196 SRC85 - PROCEEDINGS - THE 8TH SCANDINAVIAN RUBBER CONFERENCE: NEW TECHNOLOGY FOR IMPROVED DESIGN WITH RUBBER.** This Conference proceedings contains 43 papers, eight of which are in the German Language. The main topics covered are engineering design with rubber, rub-

ber-fiber composites, textile adhesion and processing for quality. Consistency of quality has been stressed because of the automation of rubber products manufacturing processes. Ways and means of improvement in the process economics and reduction in environmental pollution are analyzed. Product diversification based on modifications of polymerization to yield different polymer structure is discussed. Technical and professional papers from this conference are indexed and abstracted with the conference code no. 10204 in the Ei Engineering Meetings (TM) database produced by Engineering Information, Inc.

**092197 PRODUCTION OF HYDROXYL-TERMINATED LIQUID NATURAL RUBBER-MECHANISM OF PHOTOCHEMICAL DEPOLYMERIZATION AND HYDROXYLATION.** Photochemical degradation of natural rubber yielded hydroxyl-terminated liquid natural rubber (HTNR) when carried out in solution in presence of H<sub>2</sub>O<sub>2</sub>. Ultraviolet radiation from a medium pressure mercury vapor lamp and sunlight were found to be almost equally effective in bringing about the depolymerization and hydroxylation of natural rubber. The variations in the composition of the reagents and exposure time on the extent of depolymerization was conducted, and a suitable procedure for the large scale preparation of HTNR was described. A probable mechanism leading to the formation of HTNR as well as the side products is discussed based on the analytical data. (Author abstract) 38 refs.

**092199 RUBBER PRODUCTION OF SALT-STRESSED GUAYULE AT VARIOUS PLANT POPULATIONS.** The hypothesis that increasing the plant population of guayule (*Parthenium argentatum*) to compensate for the reduced plant canopy size caused by soil salinity coupled with an anticipated enhancement of rubber production under the moderate environmental stress imposed by salinity was tested in a field plot experiment in the Imperial Valley of California. Irrigation waters having electrical conductivities of 1.2, 3.2, 6.5, and 9.4 dS/m were applied for 4 years to plots having plant populations of 28,000, 56,000, and 84,000 plants per hectare. The influence of salinity on rubber and resin production was independent of plant population. The salt tolerance threshold, maximum average salinity level of the root zone measured as the electrical conductivity of saturated soil extracts without yield reduction, was 7.5 dS/m; beyond this threshold, rubber production was reduced 6.1 percent per unit increase of soil salinity. The hypothesis tested was proven to be false because neither increased salinity nor increased plant population increased rubber production. (Edited author abstract). 19 Refs.

**092200 UNEVEN SURFACE ABSORBED DOSE DISTRIBUTION IN ELECTRON-ACCELERATOR IRRADIATION OF RUBBER ITEMS.** Electron accelerators for industrial use are equipped with scanning devices, where the scan frequency or linear velocity along the window may vary. For example, the ELV accelerators (Institute of Nuclear Physics, Siberian Branch, Academy of Sciences of the USSR) have a scan frequency of 50 Hz, while the LUE accelerators (Electrophysical Apparatus Research Institute) have values from 0.5 to 2 Hz. In a flow technology, where the items are transported to the irradiation zone at a set rate, the speed of an item may be comparable with the scan speed, so there is substantial nonuniformity in the absorbed dose, which adversely affects the quality. The authors have examined the dose nonuniformity for long rubber items during vulcanization by means of LUE-8-SRV and ELV-2 accelerators. Results of the investigation are presented in this article. 2 refs.

#### Research

**092202 ENGINEERING WITH RUBBER.** The author shows how the buildup of basic knowledge of the behavior of rubber has evolved into an understanding of how to achieve particular properties that lead to performance required for industrial applications. A discussion is presented of the behavior of rubber which shows that nonlinear stress-strain curves, creep, and hysteresis, and its properties are influenced not only by the method of fabrication but also by its previous history. This results not only in less precision in design compared with metals but also in less consistency in properties. Factors relative to strain amplification, elastic behavior and, strength and fatigue behavior are examined. The engineering applications of rubber are also discussed. 17 refs.

Mullins, Leonard (Malaysian Rubber Producers' Research Assoc, Welwyn Garden City, Engl). *CHEMTECH* v 17 n 12 Dec 1987 p 720-727.

**092203 STATISTICAL METHODS IN RUBBER RESEARCH AND DEVELOPMENT.** The areas covered in this review are 1) statistical experimental design, 2) response surface methodology, 3) multiresponse optimization, 4) empirical and mechanistic modeling, 5) characterization of rubber property distributions, and 6) a brief review of Taguchi methods. There is some overlapping among these areas, but this classification is useful in order to cover the material in a coherent manner. Statistical methods have considerable utility in rubber research and development. Such methods are cost effective and perhaps more importantly, help the user to formulate questions in such a way as to make research programs more productive. The use of statistical methods in formulation development has been particularly fruitful.

Statistical methods help the practitioner make sound decisions in the light of often extreme variability in the data. This is especially the case when the data is fatigue, tensile strength, or some other fracture property of rubber. 125 Refs.

## Rheology

**092204 USE OF NOVEL PARAMETERS IN THE ASSESSMENT OF NATURAL RUBBER PROCESSABILITY.** A number of parameters related to rheological behavior of natural rubber may be obtained from unconventional measurements using the Mooney viscometer. These parameters have been measured on commercial samples of the major available grades of SMR. Discrimination between grades was found to be better than for more conventional parameters. The significance of the measurements in terms of consistent processability of natural rubber is discussed. (Author abstract) 5 refs.

## Shock Waves

**092206 ON TENSILE SHOCK WAVES IN RUBBER-LIKE MATERIALS.** The problem of generation of one-dimensional tensile shock waves in rubber-like materials is studied numerically and compared to the exact elastic nonlinear solution and the steady wave solution. It is shown that a rate-type semilinear visco-elastic model can describe the steepening of the wave during its propagation and a 'thickness' of the wave is naturally incorporated. An energetic criterion for the numerical stability is discussed. The numerical results point out the uncertainty (difficulty) one may encounter in measuring the dynamic Young's modulus and Maxwell-type viscosity coefficient. (Author abstract) 11 refs.

## Solubility See POLYETHYLENES—Blending.

## Solvent Extraction

**092207 BATCH PROCESS FOR SOLVENT EXTRACTION OF NATURAL RUBBER FROM GUAYULE.** Quantities of high-quality rubber gumstock, well below the permissible contaminant levels established by the Federal Emergency Management Agency (FEMA) and the American Society for Testing Materials (ASTM), have been prepared in the Food Protein Research and Development Center's Industrial Crops Solvent Extraction Pilot Plant using a batch-processing approach. Different combinations of solvents and alcohols for rubber precipitation, antioxidants, extraction temperatures, shrub sources, storage conditions, and preparation methods were investigated; and their effects on rubber material properties were evaluated. Compounding studies and physical testing have shown that the center's guayule rubber is comparable to both have a rubber and Mexican guayule rubber prepared by an aqueous extraction

method. These results confirm the overall adequacy of the process. However, a number of processing steps require initial evaluation or further 'fine tuning' to ensure development of a fully optimized processing scheme. (Edited author abstract) 10 refs.

## Strain

**092208 FILLER-LOADED VULCANISATES AND ITS INTERPRETATION IN TERMS OF THE VAN DER WAALS NETWORK.** In the first stretch filler-loaded vulcanizates suffer in general heterogeneous and irreversible deformation even under quasi-static conditions. A full understanding of these phenomena is still not yet available. It is shown that an understanding of the Mullins softening is possible by defining strain-dependent 'one-way hidden variables'. With the aid of the van der Waals model of real networks the description is then made quantitative if modes of cooperation were defined. Light is shed onto the role of the type of filler-to-rubber contacts made up, for example, by chemical bonds or by adhesion. Exceptional high degrees of universality in the deformation behavior is, nevertheless, typical for filler-loaded vulcanizates. (Edited author abstract) 36 Refs.

## Stresses

**092209 EFFECTS OF AIR AND OIL ON STRESS RELAXATION OF NITRILE RUBBER, SILICONE RUBBER AND FLUOROCARBON RUBBER.** Stress relaxation properties of nitrile rubber, silicone rubber and fluorocarbon rubber surrounded by oil (oil 2 according to ASTM 471) and air have been studied. Measurements were also made on specimens of the three materials and immersion in water. It is found that the silicone rubber degraded faster in oil than in air, whereas nitrile rubber degraded faster in air than in oil. Under compression, the restoring force relaxes most slowly for fluorocarbon rubber, and more rapidly for nitrile rubber than for silicone rubber. Treatment with water had no influence on silicone rubber, but caused a deterioration of the stress relaxation properties of the other two materials. (Author abstract) Refs.

## Structure

**092210 NATURE OF MICROCRYSTALLINE FORMATIONS AND THEIR CORRELATION WITH THE PROPERTIES OF ETHYLENE-PROPYLENE RUBBERS.** The existence of several microcrystalline zones in ethylene-propylene rubber with melting points in the 285-365°K range has been demonstrated, using DTA, calorimetry and wide angle X-ray methods. The influence of thermal prehistory on the behavior of the low temperature crystalline modifications has been studied. After annealing, the more stable ones are microcrystallites with melting points in the 308-315°K range. The presence of microcrystallites has a substantial effect on the thermo-oxidative and relaxation properties of the olefin rubbers. (Author abstract) 22 refs.

## Surface Properties See ELASTOMERS—Adhesion.

## Surfaces

**092211 EFFECT OF TREATMENT IN PLASMA ON SURFACE PROPERTIES OF SILOXANE RUBBER.** Treatment with a glow discharge was carried out in a flow of argon or oxygen at P = Pa and discharge current

of 3 mA. The surface tension was found by measuring the wetting angles of the rubber surface by various liquids and plotting the curve of the cosines of the wetting angle as a function of the value of the surface tension of the corresponding liquids. The surface tension of the polymer was found by extrapolating the curves obtained to  $\cos \theta = 1$ . (Edited author abstract)

## Swelling See Also TUBES—Rubber.

**092212 SOME COMMENTS ON THE SWELLING MECHANISM OF RUBBER VULCANIZATES.** The relationship between network structure and mechanical properties for rubber vulcanizates has been widely investigated. The authors prepared ordinary natural rubber (NR) vulcanizates and an endlinked polydimethylsiloxane (PDMS) model network. In this paper the authors compare the values of  $M_c$  for both types of samples calculated by using the conventional Flory-Rehner equation with those estimated from the new approach and discuss the swelling mechanism of crosslinked rubber. 27 refs.

**092213 KINETICS OF ABSORPTION AND DESORPTION OF LIQUID BY A RUBBER ANNULUS USING A MODEL AND SHORT-TERM TESTS.** When rubber is in contact with a liquid, the liquid may be absorbed, provoking swelling. Absorption of liquid by rubber is controlled by diffusion under transient conditions; and desorption by diffusion and evaporation. A model based on an explicit numerical analysis is described for calculating the kinetics of absorption and desorption. This model takes into account the diffusion of the liquid through the rubber in the absorption process; and the diffusion of the liquid and its evaporation from the surface during the desorption process. It has been applied with good agreement with experiments on annulus samples of rubber of various thicknesses. The relevant parameters, the coefficient of diffusion and the rate of evaporation, were previously determined by using short-term tests with thin sheets of the same rubber. (Author abstract) 10 refs.

## Testing See POLYMERS—Testing.

## Thermal Effects

**092214 THERMAL ANALYSIS OF SILICONE CAOUTCHOUC POLYMERS AND SILICONE RUBBERS, II.** It was proved experimentally that isotherms obtained from the results of isothermal thermogravimetric analysis are suitable for the characterization of silicone rubbers used in industry. The experimental results provide a possibility for the calculation of overall (apparent) reaction rate constants, characteristic of the thermal decomposition process, and for the calculation of half-life values in conjunction with the service life. Comparisons of the isotherms and of the characteristic calculated values demonstrated the effects of the parameters of silicone rubber preparation and of the conditions of application on the thermal stability. (Author abstract) 4 refs.

## Viscoelasticity See Also TIRES—Friction.

**092215 NONLINEAR VISCOELASTIC MODEL FOR REPRESENTING NONFACTORIZABLE TIME-DEPENDENT BEHAVIOR IN CURED RUBBER.** A nonlinear constitutive equation is advanced for cured rubber where the elastic and relaxation contributions to the overall response have separate generalized

deformational dependences. Predictions of viscoelastic behavior based on this theory are then compared to transient and dynamic data acquired in two strain fields on a natural rubber gum vulcanizate. It is shown that the model successfully predicts the nonfactorizability of time and strain effects observed for the large strain and the incremental strain, stress relaxation functions, and for the incremental storage modulus. However, in the case of the incremental loss modulus, these effects are observed to be factorizable, a behavior also predicted by the model. Further, the observed deformational dependence of the incremental loss tangent is well characterized by the theory. (Edited author abstract) 19 refs.

Sullivan, J.L. (Ford Motor Co, Dearborn, MI, USA). *J Rheol* v 31 n 3 Apr 1987 p 271-295.

**092216 VISCOELASTIC ANALYSIS OF LABORATORY- AND FIELD-AGED RUBBER FROM SYNTHETIC POWERLINE INSULATOR WEATHER-SHEDS.** The present investigation illustrates that viscoelasticity measurements are sensitive to modifications in the morphology of filled rubbers brought about by multi-factor aging. Tests to measure elongation at break are among the most popular to monitor degradation in rubbers; this study has shown that  $\tan \delta$  measurements of glass transition temperature can be correlated fairly well with elongation at break values of aged EPM. Therefore, viscoelastic analysis could eventually replace other conventional destructive tests. The present testing method can be considered nondestructive since only small cubes are needed. 6 refs.

**092217 SCHWEFELFREIE VULKANISATIONSSYSTEME FUER DIENKALKSCHUHE - EINE UEBERSICHT.** [Sulfur-Free Vulcanization Systems for Diene Rubber - A Review]. A systematic survey is given for the most important vulcanization systems for General Purpose Rubbers (i.e. except special elastomers like EPDM, CSM and the like). The following vulcanization processes are described: Vulcanization by sulfur donors; by chemicals with reactive chlorine atoms; by resins; by products with reactive nitrogen-containing groups (which is a big and diversified sector); by olefinic groups including so-called cyclization; by peroxides and finally by ionic groups (salt vulcanization). The author also considered the question, why sulfur vulcanization is still the predominant technology despite its well known disadvantages; there were a number of attempts to replace it by other methods; but with very limited success. (Edited author abstract) In German. 115 refs.

Kempermann, Th. *Kautsch Gummi Kunstst* v 40 n 8 Aug 1987 p 741-751.

**092218 NEW ACCELERATORS FOR VULCANIZATION OF RUBBER: PART 5. POLYMERIC THIOCARBAMOYL SULFENAMIDES.** Four polymeric thiocarbamoyl sulfenamides based on hexamethylene diamine (HMDA), 1,3-diamino propane (DAP), 1,3-di-4-piperidyl propane (DPP) and 4,4'-diamino diphenyl methane (DADPM) have been evaluated as sulfur vulcanization accelerators for NR both in the gum and the black filled stocks. Only the HMDA based polymeric thiocarbamoyl sulfenamide (PTS) appeared to offer the best activity. The efficiencies of the PTSs have been found to be significantly controlled by the level of dispersion in the rubber matrix. A correlation has been established between the relative efficiencies of the PTSs and such properties like polymer segment mass, polarity of the polyaccelerators, their melting points, etc. (Edited author abstract) 7 refs.

**092220 NEW VULCANISING SYSTEMS - A REVIEW.** Although well understood for a long time now, the vulcanization of rubbers continues to be the subject of many investigations. This review of work published in this field covers the period since that compiled by M.C. Kirkham. Many studies have been published covering both new vulcanising chemicals - accelerators and activators, retarders and other agents - and also the vulcanising process itself, particular processes for high temperature curing. The two approaches are in any case associated. Many authors who have studied for example the effects of high temperature curing have done so in order to find a vulcanisation system better adapted to today's conditions. The first part of this review covers high temperature vulcanisation and its consequences. Next follows a review of products for conventional sulphur cures (accelerators, activators and retarders), then sulphurless systems and finally the vulcanisation of specialty elastomers. (Author abstract) 50 refs.

**092221 DIPENTAMETHYLENE THIURAM TETRASULFIDE (DPTS) VULCANIZATION OF NATURAL RUBBER AT ELEVATED TEMPERATURE.** The dependences of the first order reaction rate constant, the scorch, and optimum (90% conversion) cure time from the dosage of DPTS, ZnO, stearic acid, and sulfur in a NR-Dipentamethylene thiuram tetrasulfide system has been studied. The DPTS vulcanization seems to proceed in a similar manner as the crosslinking with thiuram disulfide with the exception that the polysulfidic component is likely to contain more S-atoms than the corresponding sulfuring transition complex from thiuram disulfide. (Author abstract) 14 refs.

Das, C.K. *Kautsch Gummi Kunstst* v 40 n 9 Sep 1987 p 826-828.

**092222 CURE MODIFICATION EFFECTED BY 2-IMINOTHIOPHthalIMIDES IN THE VULCANIZATION OF NR ACCELERATED BY THIOCARBAMYL SULFENAMIDES AND DIBENZOTHIATZYL DISULFIDE.** To moderate the scorchy behavior of the binary combinations of accelerators comprising thiocarbamyl sulfenamide and dibenzothiazyl disulfide (MBTS), N-clohexylthio phthalimide (CTP) was earlier used as a retarder. Although CTP could prolong the scorch time of the recipes, at the same time it reduced the torque developed during vulcanization of NR as recorded by a Monsanto Rheometer (R-100). Obviously, the vulcanizates obtained from these retarded systems possessed poor modulus, tensile strength, torque, etc. The present investigation is an effort to improve the physical properties of the NR vulcanizates obtained with other retarders and to explore the various reactions so as to understand the mechanism of cure retardation as applicable to these systems. With this in mind, N-oxydiethylene-thiophthalimide (ODTP) and N-cyclopentamethylene thiophthalimide (CPTP) have been employed as retarders in the present investigation. 18 refs.

Dipak Kumar. *Rubber Chem Technol* v 60 n 5 Nov-Dec 1987 p 803-821.

**092223 STUDIES ON THE REACTION OF BIS-(DIISOPROPYL) THIOPHOSPHORYL DISULFIDE WITH SILICA IN THE VULCANIZATION OF NR.** The reaction between bis(diisopropyl) thiophosphoryl disulfide (DIPDIS) and silica has been investigated. The study reveals that DIPDIS can be used as a coupling agent for silica. The chemical bond between the silanol groups of silica and DIPDIS has been established through the isolation and characterization of isopropyl alcohol that is eliminated from the reaction. The chemical nature of the bond is also supported by the IR analysis of the reaction products of silica and DIPDIS obtained both in the presence and absence of rubber. From the exploratory studies it is indicated that DIPDIS can also react with NR even during mixing of ingredients. (Edited author abstract) 14 refs.

Mandal, Swapna Kumar (Indian Assoc for the Cultivation of Science, Calcutta, India); Datta, Rabindra Nath; Das, Prasanta Kumar; Basu, Dipak Kumar. *J Appl Polym Sci* v 35 n 4 Mar 1988 p 987-994.

**092224 STUDIES ON THE REACTION OF BIS-(3-TRITHOXY Silyl PROPYL) TETRASULFIDE WITH SILICA FILLER, ACCELERATOR AND NR.** Investigations have been carried out on the effect of silane coupling agent in vulcanization of NR. Bis-(3-trithoxy silyl propyl) tetrasulfide (TESPT), a representative silane compound having two reactive end groups, was used to determine its role during compounding as well as vulcanization. The studies reveal that TESPT is reactive towards NR, silica and accelerators like 2-mercapto benzothiazole and N-oxydiethylene-2-benzothiazole sulfenamide and thus throws additional light on the coupling reactions, especially in the early part of vulcanization. (Author abstract) 7 refs.

Datta, R.N.; Das, P.K.; Mandal, S.K.; Basu, K. *Kautsch Gummi Kunstst* v 41 n 2 Feb 1988 p 157-159.

**092225 STRUCTURAL ELUCIDATION OF NR VULCANIZATES CONTAINING THIOAMINES AND THIOPHTHALIMIDES AS CURE MODIFIERS.** This investigation deals with the modification of curing effected by cyclohexylthioamines and alkylthiophthalimides in the vulcanization of NR accelerated by the dual system of accelerators comprising thiocarbamyl sulfenamides and dibenzothiazyl disulfide. There exists a correlation between the various sulfidic linkages and the physical properties of the vulcanizates, e.g. torque, modulus and tensile strength. It is apparent from the investigation that thioamines greatly modify curing and improve the heat and age resistance behavior of the vulcanizates and are better than thiophthalimides in this respect. (Edited author abstract) 11 refs.

Das, P.K.; Datta, R.N.; Basu, D.K. *Kautsch Gummi Kunstst* v 41 n 3 Mar 1988 p 236-238.

**092226 FROM VULCANIZATION MODEL TO PROCESS CONTROL.** The simulation of the vulcanization process is leading to increased insight into process behavior in terms of temperature, time, and degree of cure. A model is presented which has been built with the minimum of compromise to the physics of this process. The ultimate goal is to develop a quantitative prediction of the vulcanization process with an accuracy of  $\pm 5\%$  in the degree of cure, which will lead to optimal process control in the near future. 18 refs.

Veltman, B. (Nederlandse Philips Bedrijven BV, Eindhoven, Neth); van Hastenberg, C. *Rubber Chem Technol* v 61 n 1 Mar-Apr 1988 p 64-77.

**092227 PRACTICAL CONSIDERATIONS OF ACCELERATION BASED ON THEORY.** Various practical considerations related to the selection and use of accelerators have been discussed. These include the effect of accelerator type, loading, cure temperature, activators,

retarders, postcrosslinking agents, dispersion and solubility on vulcanizate properties. Many of these effects have been linked to the theoretical view of accelerated sulfur vulcanization in an effort to make these concepts more generally applicable. (Edited author abstract) 21 refs.

Lay, Robert W. (BF Goodrich Co, Brecksville, OH, USA). *Elastomerics* v 120 n 5 May 1988 p 21-26.

**092228 SULFUR VULCANIZATION WITH TWO PLATEAUS - FORMATION OF AN INHIBITOR DURING VULCANIZATION?** Efficient sulfur vulcanizing systems based on thiazolesulfenamide accelerators derived from secondary amines show unusual and complex vulcanization kinetics in NR. This feature does not appear to have been reported previously. Depending on the nature and purity of the accelerator, the ratio of accelerator to sulfur, the cure temperature, the type of rubber being used, and the presence of other additives, two distinct periods of crosslinking may be evident, separated by a more or less well-defined plateau. This plateau is longer and more distinct if the accelerator is pure, its ratio to sulfur is high, the cure temperature is low, and there are no other additives present. Sulfenamide accelerators derived from both primary and secondary amines may give rise to this behavior in rubbers other than NR. The observed behavior has been shown to be due to the formation, during the first cure period, of an extractable crosslinking inhibitor. 15 refs.

Loo, C.T. (Rubber Research Inst of Malaysia, Kuala Lumpur, Malays); Porter, M.; Tidd, B.K. *Rubber Chem Technol* v 61 n 2 May-Jun 1988 p 173-185.

**092229 NONISOTHERMAL VULCANIZATION OF RUBBER COMPOUNDS.** The present work is devoted to theoretical and experimental investigations of the isothermal and nonisothermal vulcanization of rubber compounds. A nonisothermal vulcanization kinetic model has been proposed. In particular, this model can easily be implemented in the analysis of the injection molding process of rubber compounds. The model has been verified in nonisothermal experiments including both homogenous and nonhomogenous vulcanization of rubber compounds, and can be applied to any nonisothermal processing operations, including vulcanization of tires. 22 refs.

Isayev, A.I. (Univ of Akron, Akron, OH, USA); Deng, J.S. *Rubber Chem Technol* v 61 n 2 May-Jun 1988 p 340-361.

**092230 SULFUR-FREE VULCANIZATION SYSTEMS FOR DIENE RUBBER.** The sulfurless crosslinking of natural and synthetic rubber to form vulcanizates is an extensive field which even a survey cannot treat exhaustively. This paper will, therefore, be confined to diene rubbers important in tire production (NR, IR, SBR, BR), except for occasional references to polychloroprene (CR). As will be shown, even this restriction leaves an exceptionally large number of fundamental possibilities; to some extent, therefore, a bibliography will have to suffice. Various vulcanization systems have been discussed. Some of the vulcanization agents covered include thiourea, bis-mercapto compounds, reactive chlorine compounds, thiuram, reactive nitrogen compounds, and peroxides. 115 Refs.

Kempermann, Th. (Bayer AG, Leverkusen, West Ger). *Rubber Chem Technol* v 61 n 3 Jul-Aug 1988 p 422-447.

**092231 CONTINUOUS VULCANIZATION PROCESSES.** In order to increase the output of extruded rubber parts usually vulcanized in a second stage, let us say the batch process cycle, various continuous vulcanization systems have been developed. In the most recent period of development, the continuous vulcanization process has gained in importance. The following continuous systems are known: vulcanization in a steam pipe, vulcanization in a hot air tunnel, vulcanization in a salt bath, vulcanization in a fluid bed, UHF (microwave) vulcanization, shear head extrusion, and radiation vulcanization. The author briefly reviews each one of these processes.

Herlaut, Elisabeth (France Elastomerics). *Rubber World*

v 198 n 4 Jul 1988 p 20-22.

**092232 UNIFORMITY BY MICROWAVE.** Microwave heating offers an efficient, clean and rapid way to bring even the most awkwardly shaped extrusion up to cure temperature on a continuous basis. It offers particular benefits in terms of cure uniformity as most rubber compounds can be formulated to optimize microwave penetration/absorption. Microwave penetration depends on the power of the microwave source and on the absorption properties of the material. Microwaves can totally penetrate extruded components made from polar rubber compounds, so that all of such extrusions is subjected to their effects. The process' principal disadvantage is that microwave is a pre-heating technique and not a full vulcanization system. Capital investment is rather higher with microwaves than with alternative systems, but this outlay is justified by the large energy savings possible with this method.

Tedesko, Peter (Cim d'Or SA, Spain). *Eur Rubber J* v 170 n 7 Jul-Aug 1988 p 27.

**092233 MICROWAVE VULCANIZATION FOR GOOD, CONSTANT AND RELIABLE PRODUCTION RESULTS.** It is argued that to produce good microwave-vulcanized rubber extrusions it is necessary to pass them through a microwave tunnel, thus bringing the product up to the vulcanizing temperature, and then through a hot-air tunnel to reach the proper degree of vulcanization. The article deals first with the problem of determining the power requirements of the UHF tunnel and the length of the hot air tunnel.

Tedesko, Peter (CIM-DOR Corp, Spain). *Rubber World* v 198 n 6 Sep 1988 p 27-30.

## Wear

**092234 FRACTAL ANALYSIS OF RUBBER WEAR SURFACES AND DEBRIS.** The wear surface and debris of three rubber compounds (NR, PBD and NR/PBD/SBR), worn on a modified blade abrader, were fractal. The fractal dimension of the wear surface was: (1) limited to a finite range, and if the wear mechanism remained the same; (2) independent of the wear load; and (3) the basis for creating a master fractal plot by a shift factor that (4) decreased linearly with wear load. The fractal dimension of wear was determined on the basis of profilometer traces and showed that the wear load affected the scale of the wear process. The fractal dimension of the debris also increased with the wear load and is thought to be a function of the agglomeration mechanism during wear. (Author abstract). 18 Refs.

**RUBBER COMPOUNDING** See Also ELASTOMERS—Mechanical Properties; RUBBER; RUBBER—Additives; RUBBER—Crosslinking; RUBBER—Curing; RUBBER—Fillers; RUBBER—Ozone Resistance; RUBBER—Solvent Extraction; TIRES—Materials.

**092235 COMPOUNDING NATURAL RUBBER FOR LOW ROLLING RESISTANCE IN INDUSTRIAL SOLID TYRE APPLICATIONS.** Vulcanizates for industrial solid tires with low rolling resistance require low hysteresis, high modulus and good wear properties, together with a high degree of reversion resistance in order to minimize the adverse influence of long vulcanizing times. The progressive compounding stages to achieve these properties are demonstrated. Further improvements in rolling resistance characteristics can be achieved through alternative compounding techniques, though at the expense of wear and tear properties. The ideal tire construction would be a dual compound comprising a reversion-resistant tread cap with good wear performance and low hysteresis, and a high modulus base compound to enhance the low rolling resistance. (Author abstract) 2 refs.

Wallace, I.R. *NR Technol* v 18 pt 3 1987 p 61-66.

**092236 PREPARATION AND EVALUATION OF MULTIFUNCTIONAL RUBBER INGREDIENTS.** Modified epoxidized linseed oil compound with aniline and phenylhydrazine were prepared. These compounds are macromolecules and have the advantages that they are nonvolatile, do not bloom to the surface of rubber and can be homogeneously distributed in rubber mixes. The prepared compounds behave as multifunctional rubber ingredients. The results reveal that they have showed in NR a good accelerating efficiency compared with MBT, as plasticizer compared with processing oil and as antioxidant compared with PBN. The extended study for these compounds in SBR mixes showed that they behave as a good antioxidants and plasticizers, but as weak accelerators. (Author abstract) 8 refs.

## Additives

**092238 POLYMER-BOUND ANTIDEGRADANTS: A BETTER WAY TO LOCK IN HIGH PERFORMANCE.** This article will review: (a) reasons that polymer-bound antidegradants were first developed; (b) selected advances in the field during the last five years; and (c) special compounding considerations in their use. Polymer-bound antioxidants can be grouped according to the methods used to build the antidegradant into the polymer network. Methods include: (a) copolymerization, (b) reaction with a pendant active group and (c) reaction of a highly active group on the antidegradant with standard polymer functionality. Current work in the field is focused primarily on three areas: 1) copolymerization, 2) attachment of radicals to diene polymers and 3) reactions of antidegradants with epoxidized polyisoprene. The reaction of sulfur radicals is discussed and epoxidized polymer and rubber compounding are outlined. 21 Refs.

## Process Control

**092240 RHEOLOGIC SOFTWARE - A TOOL TO ASSIST IN THE SPC OF RUBBER MIXING.** A trend has emerged in the rubber industry toward the implementation of statistical process control (SPC). Customers are no longer content with the knowledge that a product meets specification. They are demanding that the product be as free from variation as the intended use demands. The authors discuss how the addition of a RheoLogic package to the Monsanto oscillating disc rheometer has enabled Veray Laboratories to move from having a piece of test equipment into having a valuable tool. 1 ref.

Russo, Stephen (Vernay Lab); Di-Mauro, Patrick J.; Braver, John I. *Rubber World* v 197 n 4 Jan 1988 p 14-17.

Research See RUBBER—Research.

## Rheology

**092241 RHEOLOGICAL BEHAVIOR OF RUBBER CARBON BLACK COMPOUNDS IN VARIOUS SHEAR FLOW HISTORIES.** The rheological properties of rubber carbon black compounds are studied in various shear flow histories. In particular we studied (i) stress relaxation, (ii) transient and steady state shear flow, (iii) stress relaxation after steady flow, (iv) sequential shear flow history, (v) storage effects, (vi) programmed step shear histories. At low carbon black concentrations, the rheological response is similar in character to that of unfilled elastomers. For carbon black concentrations of 20 percent by volume and above, the compounds exhibit yield values which increase with carbon black concentration and decreasing particle size. The rubber carbon black compounds exhibit 'hysteresis loops' in programmed step shear histories and rheological property growth in storage experiments. (Author abstract), 26 Refs.

## RUBBER FACTORIES

**092242 USE OF FLUIDIZING TECHNIQUES IN PNEUMATIC HANDLING OF PROCESS MATERIALS.** Mention fluidization in the rubber and plastics industry and the mind almost instantly connects it with the Rapra designed fluid bath. Fluidization of carbon blacks and processing powders to make them handle is an entirely different matter. Basically, it is the passage of low pressure air through a permeable membrane. When the membrane is set at an angle (min 3°) with black or powder on it, passage of air through the membrane breaks down the frictional resistance between membrane and powder, causing it to flow like water in the down slope direction. At this point, a practical demonstration of fluidization techniques on a model airslide may help to give a better understanding of this article.

Computer Applications See RUBBER—Manufacture.

Process Control See Also RUBBER MACHINERY—Molding Machines.

**092243 PROCESS CONTROL EVALUATION IN ACCORDANCE WITH AUTOMOTIVE INDUSTRY REQUIREMENTS.** The elements of process control are after-pressure regulation: via the work input for injection curing time regulation. The objective of these controls is to make sure that the quality of the article is the same shot after shot. In addition the state-of-the-art in process control is: regulation of the screw speed - which is standard in extruder technology - and regulation of the back pressure. 6 refs.

RUBBER INDUSTRY See Also RUBBER—Manufacture.

## Chemical Analysis

**092245 MODERN ANALYTICAL METHODS USED IN THE RUBBER INDUSTRY - THE POLYSAR EXPERIENCE.** Many new analytical techniques, invariably faster and more powerful than the old ones, have been developed. A brief description of the regularly used techniques, including modern spectroscopic, chromatographic, and microscopic methods are given, with some examples of application. Also included is a discussion about the logical approach in problem solving situations. (Edited author abstract)

Chu, C.Y. *Kautsch Gummi Kunstst* v 41 n 1 Jan 1988 p 33-39.

Computer Applications See RUBBER—Manufacture.

## Europe

**092246 INCREASING IMPORTANCE OF SPECIALTY ELASTOMERS IN WESTERN EUROPE.** The increasing use of special rubbers is determined less by completely new applications than by their role as substitutes for the elastomers that can no longer meet more stringent demands. The discussion is restricted to the West European market, which is typical of other industrialized regions in development and applications of special elastomers. In some of the technologically demanding areas of elastomer application, especially the automobile sector, Western Europe is often a trend setter. 6 refs.

Casper, R. (Bayer AG, West Ger); Rhode, E. *Elastomerics* v 120 n 4 Apr 1988 p 11-16.

**092247 ZUNEHMENDE BEDEUTUNG DER SPEZIALKAUTSCHUKE IN WESTEUROPA.** [Increasing Importance of Special Rubbers in Western Europe]. A review of the present situation on the Western European market is followed by a prediction of the future development of special rubbers - which in the last ten years have accounted for most of the growth in the elastomer field. The prospects of the various special rubbers, expressed as the relation between a performance number and price, are estimated. The increasing importance of this group of rubbers results from the substitution of materials that are no longer adequate, either because the technical demands made on them have become too severe or because more stringent safety requirements have been introduced. The substitution processes and their causes are discussed more fully with reference to applications in motor vehicle under-the-hood applications and in cables. (Edited author abstract). 6 Refs. In German.

Plantations See Also RUBBER—Molecular Weight; RUBBER—Production.

**092248 SEASONAL CHANGES IN RUBBER AND RESIN CONTENTS IN CHRYSOTHAMNUS**

**NAUSEOSUS SSP. HOLOLEUCUS AND SSP. TURBINATES.** *Chrysanthamnus nauseosus* (rubber rabbit-brush) is a desert shrub that grows in high density in large populations over a wide range of environmental conditions in the western United States and contains natural rubber that has potential commercial value. Individual plants of two sympatric subspecies (*turbinatus* and *hololeucus*) were analyzed to determine the distribution of rubber and resin within the plant. The highest rubber and the lowest resin contents were in the stems near the soil level whereas the highest resin and lowest rubber were in the top of the plants. Negative correlation between rubber and resin from top to bottom of the plants was significant for ssp. *turbinatus*. During the growing season, the highest rubber and lowest resin contents occurred during the summer for both subspecies. In contrast the highest resin and lowest rubber contents occurred in the spring for both subspecies. Negative correlation between rubber and resin for one year old tissue in ssp. *turbinatus* was very significant. (Edited author abstract). 12 Refs.

Hegerhorst, D.F. (Brigham Young Univ, Provo, UT, USA); Weber, D.J.; Bhat, R.B.; Davis, T.D.; Sanderson, S.C.; McArthur, E.D. *Biomass* v 15 n 3 1988 p 133-142.

**092249 SALT TOLERANCE OF IRRIGATED GUAYULE.** The salt tolerance of guayule (*Parthenium argentatum* Gray cv. N565-II) was tested in small field plots (silty clay soil) in the Imperial Valley of California. Seedlings were transplanted in October 1981. Differential salination was begun in March 1982 and continued for 4 years by irrigating with waters salinized with NaCl and CaCl<sub>2</sub> (1:1 by wt.) to obtain electrical conductivities of 0.8, 1.4, 3, 6, 9, and 12 dS/m. Dry matter, rubber, and resin yields were determined from pollarded plants in February 1984 and uprooted plants in February 1985 and 1986. Rubber concentrations in the woody branches in 1984 and 1985 averaged 6.1 and 7.3 percent, respectively on a dry weight basis and were not significantly affected by soil salinity. Resin concentrations averaged 8.6 percent and 7.3 percent for the two years. In 1986, both rubber and resin concentrations decreased with increased salinity. Plant mortality rather than growth reduction at high levels of salinity appears to be the limiting factor for rubber production from irrigated guayule. (Edited author abstract). 15 Refs.

Maas, E.V. (USDA, Riverside, CA, USA); Donovan, T.J.; Francois, L.E. *Irrig Sci* v 9 n 3 1988 p 199-211.

## Waste Utilization

**092250 EQUIPMENT FOR SHREDDING RUBBER SCRAP.** A range of machines has been developed for shredding rubber scrap and discarded rubber articles into crumbs. These machines are intended for shredding vulcanized pressure-rubber parts, used rubber articles, and scrap from the shoe industry. The machine has a knife-type shredder which converts scrap into crumbs of 6-8 mm size, and a disk mill which converts the large crumbs to a particle size not exceeding 2 mm. If necessary, the scrap can be processed in the knife-type shredder alone to get crumbs of 6-8 mm size. The production line for rubber crumbs consists of a magnetic separator, shredding unit, vibratory separator, two magnetic separators, hopper, packing unit, and four pneumatic transport systems. Another important project was the development of equipment for reclaiming worn tires with metallic and textile cords. A machine (type 142.041) has been developed and successfully tested for cutting tires with metallic cord. It consists of two cutter shafts (rotating towards each other) mounted in housings which are connected by a common frame. 1 ref.

**RUBBER MACHINERY** See Also RUBBER INDUSTRY—Waste Utilization; RUBBER PRODUCTS—Manufacture.

**092251 EQUIPMENT FOR PROCESSING POLYMERIC MATERIALS AND PAPER AND PULP PRODUCTS EQUIPMENT FOR THE MANUFACTURE OF RUBBER SCREENS.** Equipment for the production of rubber screens with mesh size  $40 \times 40$  mm has been developed. The equipment comprises a machine for making rubber screens MIRS-40, No. 442.031 and a machine for cutting flash MVO-40, No. 642.041. The machine for the manufacture of rubber screens MIRS-40 consists of a shaping drum fixed in bearing blocks on a bed, which contains two side walls, fastened with braces, from clamping and deflection drums covered by a steel band. A shield is installed to protect the rubber mixture being fed in from prevulcanization. The machine is equipped with a system of electric heating, which supplies the necessary heat for warming the machine, setting it to a given temperature schedule, and maintaining a working temperature during operation.

**Mixers** See Also RUBBER—Mixing.

**092256 SELECTION OF OPTIMAL DESIGN OF SCREW MIXER FOR PRODUCTION AND CONVERTING RUBBER MIXTURES.** The process of producing rubber mixtures from powder composites and the simultaneous molding of semiproductions in screw mixers is the most promising process for converting rubber mixtures. The authors carried out comparative investigations of six types of screw mixers with screws with diameter  $D = 80$  mm and length  $L = 9-10 D$  (with the exception of the extended screw with a three-start eccentric thread for which  $L = 16 D$ ). To compare and evaluate the machines, the authors adopted four parameters of the process as criteria: output of the machine  $G$ , final temperature of the mixtures  $T$ , specific energy expenditure on conversion of the mixtures  $q$ , and also the quality of the processing of the mixtures. Results show that the best quality of conversion is ensured by the machine with an elongated three-start screw when fed with compacted and powdered composite. Investigational results were used to design screw mixers. 8 refs.

Bagno, A.I.; Bastrygin, V.V.; Zoroastrova, M.A.; Damov, A.S. *Chem Pet Eng* v 22 n 11-12 Nov-Dec 1986 p 533-535.

**092257 MIXING PERFORMANCE OF MIXER FOR RUBBER.** New technology has been developed for improving the mixing performance of an internal batch mixer, using a 16 l-size mixer equipped with a new type of 4WH rotor operated in a mode of optimum orientation even-speed mixing at a higher rotation speed. Further modifications and improvements regarding rubber-mixing technology are also reviewed, including: (a) precise production of rotors with CAD and CAM, and modification of rotor material; (b) application of a micro-processor to a new automatic mixing controller; and (c) energy-saving devices (mechanical floating weight and mini-oil dust stop). (Author abstract) 1 ref. In Japanese.

Hagiwara, Katsunobu; Hamada, Yoshihiro; Asai, Toshihiro. *R&D Res Dev Kobe Steel Ltd* v 38 n 2 Apr 1988 p 28-31.

**092258 ACQUISITION AND APPLICATION OF DATA OBTAINED DURING THE MIXING CYCLE OF AN INTERNAL BATCH MIXER.** The emphasis in polymer processing and fabrication has been placed upon product uniformity and consistency in the pursuit of improved quality. To accomplish this goal we first must understand the implication of these parameters to the actual process. To define any processing operation there are two components, a fixed mechanical configuration of equipment and a set of variable operating conditions for this equipment. The data which are obtained from the batch mixer provide a dual function: a) to record the processing conditions for documentation, and b) on line indication and control of the operating conditions for the batch mixer. The control systems for batch mixers can benefit from advancements in data acquisition as these parameters are utilized in complex reactive feedback control logic. The better equipped we are to obtain, interpret and apply the data from the batch mixer, the easier it will be to increase processing uniformity.

**Molding Machines** See Also RUBBER PRODUCTS—Molding.

**092259 FROM TRANSFER TO INJECTION MOLDING: HOW ONE COMPANY DID IT.** Monarch Rubber recently recognized the need for new manufacturing technology that could help: improve product performance and durability; assure continued product quality through statistical process control aided by micro-processor technology; and improve productivity and reduce costs. Monarch believed all three areas should be attacked simultaneously to maintain their competitive market position. The company launched a major expansion project, enlisting the help of equipment supplier French Oil Mill Machinery. The two companies explored a total systems approach through research and development of alternative molding processes for Monarch's line of vibration control devices. The result was an improved ability to provide customers with the highest-quality parts at good value.

Anon. *Elastomerics* v 120 n 6 Jun 1988 p 28-32.

**092260 BLASTING BY METAL BEADS.** In general terms, using Metalbead and a manually operated, suction feed rubber mould cleaner, a typical  $1 \text{ m}^2$  multicavity segmented mould can be cleaned in less than ten minutes with no change in crucial dimensions. This compares with six hours with acid or chemical methods. Metalbead, unlike glass bead, will not become trapped in vent holes. It therefore will not be brought back to the press and risk contaminating raw stock. The grade of Metalbead will be selected according to the type of rubber mould cleaner specified and the feed method. Suction and pressure feed cabinets are capable of handling moulds up to about  $1 \text{ m}^2$ . Because some moulds are very heavy, a side-loading turntable trolley is used to ease loading and manipulation inside the cabinet.

**092263 THERMODYNAMISCHE ASPEKTE BEI DER VULKANISATION VON GUMMIFORM-TEILEN.** [Thermodynamic Aspects of Curing Molded Rubber Parts]. The vulcanisation of molded rubber parts - their manufacture from the physical standpoint - is a thermodynamic process. Assuming that a complete cross-link is always wanted, then time is a dependent value and assuming that the composition remains constant, then the values pressure and temperature determine the process. The influence exerted by both values on the make-up of molded rubber parts is illustrated separately by two examples. Calculation results are discussed, using an example for thermic interpretation. These results are achieved by employing the Finite Element Method, have specific characteristics and give indications of general importance to the process engineer. In addition, they show which possibilities are offered by employing these calculation methods. (Edited author abstract) 8 refs. In German.

Masberg, U. *Kautsch Gummi Kunstst* v 41 n 4 Apr 1988 p 353-358.

**092264 INCREASE IN THE STATE OF CURE IN VULCANIZATES AFTER REMOVAL FROM THE MOLD.** The progress of cure reactions was observed for rubber sheets during the cooling period after their extraction from the mold. The study was performed by considering either motionless air at 125°C and water at 12°C for cooling the rubber previously cured in a mold kept at 160°C. A significant increase in the state of cure was calculated with the help of a numerical model for the vulcanizates, especially in the case of air at 125°C. An improvement in physical properties such as the swelling in toluene, and mechanical properties measured either under static or dynamic conditions, was determined. (Edited author abstract). 22 Refs.

Khouider, A. (Univ of St. Etienne, St. Etienne, Fr); Vergnaud, J.M. *J Polym Eng* v 8 n 1-2 Jan-Jun 1988 p 19-37.

**092265 INCREASE IN THE STATE OF CURE IN RUBBER SHEETS DURING THE COOLING PERIOD IN WATER.** This paper shows that an increase in the state of cure is obtained within the material during the cooling period in water. Although the progress in the cure is not so large as that occurring when the material was cooled in motionless air, it is still significant especially for large samples. As the state of cure is increased at the midplane of the material or in the surrounding part of the midplane, this fact could reduce the steepness of the gradients of state of cure, making the rubber more homogeneous as far as the state of cure was concerned. Various factors were found to be of importance, and especially the thickness of the material, the motion of the water, and the value of the state of cure when the rubber was extracted from the mold. (Edited author abstract). 14 Refs.

**Extrusion** See Also RUBBER MACHINERY—Extruders.

**092266 PROFILE EXTRUSION AND VULCANIZATION.** A complete line for extruding and vulcanizing rubber profiles (300-400 kg/h) is presented. The product's specification, dictated by the profile's build-up and properties, is the main factor determining overall technical

expenditure for a continuously operating production line. Considering the actual market trend, especially in the automotive industry, profile manufacturers are urged to improve their products with regard to constancy of their dimensions and physical properties. A long-term realization of these requirements is only possible by developing a well aimed machine optimization, by analyzing parameters and their effects, and by concentrating on the application of process control systems. Each machine unit was systematically checked and determined optimal parameters applied to the complete line; on this basis an appropriate overall control system concept was developed.

## Fire Protection

**092267 UNIQUE FIRE PROTECTION USING RUBBER-BASED MATERIALS.** Fire protective elastomeric materials are used in construction for a wide range of applications. These uniquely engineered materials can be used to meet fire codes and to comply with current and proposed fire test standards. Applications include fire protection of penetration seals in fire rated floors and walls, electrical and telephone poke-through devices and electrical raceways in the nuclear and petrochemical industry. The use of a unique rubber compound based on chloroprene and intumescent technology is presented.

**Manufacture** See Also ELASTOMERS—Testing; RUBBER MACHINERY; THERMOPLASTIC ELASTOMERS.

**092268 PRESSES FOR VULCANIZING INDUSTRIAL RUBBER PRODUCTS.** A new type of pressing equipment has been developed. This equipment is intended for shaping and vulcanizing joints in rubber-fabric blanks. Data has also been generated for selecting the optimum operating parameters and for designing hydro-mechanical vulcanizing presses to suit joint lengths of 2 to 40 m. The main operating parameters which affect the working of the press are the unit molding pressure, temperature, and vulcanizing duration. The presses consist of a base, stationary, and movable heating platens, link-lever mechanism for moving the upper platen, mechanism for feeding the workpiece into the operating zone, hydraulic power pack, and control cabinet. The presses can work either in automatic, or in manual modes. 5 refs.

## Modification

**092269 MECHANIZING THE DIFFUSIVE MODIFICATION OF INDUSTRIAL RUBBER ARTICLES.** Diffusive saturation of industrial rubber articles (IRA) with inhibitors greatly enhance their resistance to various types of aging and helps economize the consumption of deficient components. One of the promising directions of diffusive modification is the use of compositions based on organosilicon polymers which make for favorable redistribution of inhibitors between the saturating shell and the IRA. To overcome the deficiencies and mechanize the process, equipment was designed and built for the dynamic modification of the IRA. The process duration for attaining the given inhibitor concentration in the vulcanizers is primarily determined by kinetic equations of diffusive saturation of the given IRA. 3 refs.

**092272 PRIMER ON CUSTOM MIXING AND MOLDING: THE QUALITY EQUATION.** In the custom mixing and molding field the two principal manufacturing operations and the areas of technical input and responsibility usually accepted are: 1) mixing of the rubber compound and testing for vulcanization characteristics; and 2) molding of the rubber product and examination for visual faults along with testing for specific mechanical properties such as hardness, deformation and stiffness. A discussion is presented of custom mixing methods along with the pros and cons of three basic processes for molding rubber products. The three processes are: compression molding, transfer molding and injection molding. 3 Refs.

## Vibrations

**092274 ON THE ROLE OF NON-LINEARITY IN THE DYNAMIC BEHAVIOUR OF RUBBER COMPONENTS.** Rubber components are frequently used in automotive applications as isolators, bushes, mounts or springs, usually bonded to steel end pieces and usually where very specific dynamic behavior is required for anti-vibration purposes. The force/deflection behavior of rubber is in general non-linear. Design of rubber engineering components conventionally seeks to suppress or avoid the effects of nonlinearity over the operating range of the component. Alternatively if the consequences of nonlinearity for dynamic behavior are understood well enough, then it is possible to exploit its effects in novel ways to enhance the performance of rubber components. In this paper the basic features of the dynamic mechanical properties of rubber are discussed together with consideration of the way they may be influenced by nonlinear force/deflection behavior. The advantages that may be gained from nonlinearity are illustrated by the performance of a recently developed automotive suspension system. (Author abstract) 5 refs.

## Viscoelasticity

**092275 VISCOELASTIC PROPERTIES OF STRUCTURAL SILICONE RUBBER SEALANTS.** This paper presents a theoretical approach used to predict the behavior of silicone rubber under uniaxial stress fields. The model is based on the concept of the classical Maxwell treatment of viscoelasticity and stress relaxation behavior. However, the Hookean spring component of the Maxwell element is replaced with an ideal elastomer component. With this substitution, the new model permits the crosslink density of the silicone elastomer to be estimated from test data and allows a stress level to be predicted as a complex function of extension, crosslink density, absolute temperature, and relaxation time. Simple uniaxial tensile tests were performed on two commercial silicone rubber sealants. Their experimental behavior was compared to the predicted performance based on the new viscoelastic model. Agreement was found to be quite good. (Edited author abstract). 13 Refs.

**092277 MAKING ISOPRENE FROM N-BUTENES.** Isoprene can be made by regioselective hydroformylation of 2-butenes to 2-methylbutanal followed by dehydration or, alternatively, hydroformylation of isobutene to 3-methylbutanal followed by dehydration. However, as is discussed, dehydrating aldehydes that are not branched at the 2-position is much less selective than with 2-branching. Thus, the more practical approach with respect to isoprene is to proceed via hydroformylation of 2-butenes to

2-methylbutanal. The authors show that dehydration of aldehydes and ketones of appropriate structure can be a selective route to dienes. When this chemistry can be combined with an efficient process for generation of the aldehyde or ketone such as hydroformylation, then an economically attractive route to diene can be achieved. 8 refs.

Forster, Denis; Sluka, James P.; Vavere, Atis. *CHEM-TECH* v 16 n 12 Dec 1986 p 746-751.

**092278 SORPTION AND DIFFUSION OF WATER IN ETHYLENE-PROPYLENE DIENE RUBBER IN PRESENCE OF VULCANIZATION ACCELERATORS.** The authors have studied the diffusion and sorption patterns of water vapor by the ethylene propylene diene elastomer SKEPT-40 and its composites with vulcanization accelerators in the activity interval of the vapor  $0.1 < p/p_s < 0.85$ . It is shown that the water sorbed by the polymer is in the matrix in three states: bound, clustered and free. The  $p/p_s$  intervals within which the particular states of sorbed water in the elastomer may be realized are determined. (Author abstract) 17 refs.

**092279 CHARACTERIZATION OF RUBBER PARTICLE SIZE DISTRIBUTION OF HIGH-IMPACT POLYSTYRENE USING AN IMAGE ANALYSIS METHOD.** Accurate characterization of high-impact polystyrene (HIPS) rubber particle size distribution has been achieved using an automatic image analysis system. The new method involves preparation of a microscope slide consisting of a dilute suspension of HIPS particles in a polymer matrix. Images of silhouetted rubber particles of true diameter are obtained using an image processor and particle size calculations can be made with a minimum of editing of the binary image. The new method provides measurement of true rubber particle diameters because the particles in the prepared slide are not swollen by an solvent. (Author abstract). 5 Refs.

Hall, R.A. (Amoco Chemical Co, Naperville, IL, USA). *J Appl Polym Sci* v 36 n 5 Aug 20 1988 p 1151-1155.

## Abrasion Resistance

**092280 FORMATION OF ABRASION PATTERNS AND THE WEAR OF RUBBER.** Wheels of an unfilled isoprene rubber and a carbon-black natural rubber were rubbed against a cylinder or a razor blade, and the formation mechanisms of abrasion patterns and the wear mechanisms of rubber were examined. When the abrasion patterns were formed on the rubber surfaces, small particles by roll-formation were observed in the early stage of wear. They grew up to relatively large in size and adhered to the rubber surface. Then cracks were formed just beneath the front portion of the adhered particles and grew large to form a series of the abrasion patterns having saw teeth. During motion of the slider the teeth are bent backwards, thus exposing their underside to the action of the slider. (Edited author abstract) In Japanese. 38 refs.

## Additives See RUBBER PRODUCTS—Aging.

## Aging

**092281 ADVANCED SYSTEM FOR EPICHLOROHYDRIN RUBBER VULCANIZED WITH TRI-AZINE THIOLS.** This article describes a new type of epichlorohydrin rubber, epichlorohydrin-ethylene oxide-allyl glycidyl ether terpolymer (GECO), named Gecron 3100 series, as well as its ancillary curing agent called ZISNET-F, or 2,4,6-trimercapto-S-triazine (triazine F). This combination, compared with conventional epichlorohydrin rubber, has not only excellent heat and ozone resistance but also excellent compression set resistance. Consequently, in Japan GECO/triazine F epichlorohydrin compounds have become the major material for

the manufacture of emission control hose tubes, exhaust gas control components and diaphragms. In this article, the authors describe the improvements achieved in aging properties as a result of the combined use of this new epichlorohydrin rubber and the new vulcanizing agent, especially with regard to compression set and heat resistance. 6 refs.

**092282 STUDIES ON THE AGEING OF EPDM BASED ROCKET INSULATOR COMPOUND BY STRESS RELAXATION AND THE EFFECT OF PROPELLANT BINDER.** The stress relaxation of unaged and aged solid propellant insulator compound based on EPDM has been investigated. The effect of a thin coating of hydroxy-terminated polybutadiene (HTPB) rubber on the insulator compound has also been studied. The results indicate that for EPDM gum vulcanizate, stress relaxation occurs due to physical flow of rubber chains and an interchange reaction of polysulfidic linkages, particularly at high temperature. However, stress relaxation data for asbestos fiber and cork filled compounds and the insulator lie on two intersecting straight lines, indicating physical relaxation processes. The first line, of greater slope ( $< 200$  s), is attributed to rearrangement/reorientation at the rubber-filler interface. On ageing, the rate of relaxation decreases for asbestos and cork filled compounds, indicating an enhancement in rubber-filler interaction. However, the coating of HTPB serves as a protective layer in the relaxation process for the insulator compound under stress. (Author abstract) 10 refs.

## Amorphous See RUBBER—Amorphous.

## Antioxidants See Also ANTIOXIDANTS—Polymerization.

**092283 STABILISATION OF EPDM AT HIGH TEMPERATURES BY POLYMER-BOUND ANTIOXIDANTS: III. EVALUATION OF MASTER-BATCH CONCENTRATES.** Concentrates of two polymer-bound arylamine antioxidants (MADA-B and MPDA-B) in EPDM (2 g/100 g) were found to be rather more effective than MADA-B made by the normal treatment of the whole rubber at the same concentration. They are also shown to be considerably more effective than conventional arylamine antioxidants (Nugard 445 and Flectol H) under a range of high temperature tests designed to simulate the severe conditions to which the rubbers are exposed in seals and gaskets. A practically relevant contamination test in which the rubbers are subjected to contact with a hydraulic fluid (Skydrol) before exposure to high-temperature aging has been found to provide a means of discrimination between different antioxidants. (Author abstract) 8 refs.

**Blending** See Also NYLON POLYMERS—Blending; POLYETHYLENES—Reinforcing; RUBBER—Blending.

**092285 MORPHOLOGY AND PROPERTIES OF BLENDED NBR/PVC/BR ELASTOMERS.** Nitrile rubber (NBR) has good oil resistance, but lacks ozone resistance. Addition of polyvinyl chloride (PVC) leads to a rubber-plastic mixture which may have more desirable properties. In order to increase the elasticity of NBR/PVC elastomers the authors have developed a method of addition of butadiene rubber (BR) to compose ternary elastomers. The novel elastomer has been fabricated into oil-resistant gaskets and driving belts. It appears that the composition has a significant economical advantage over currently used materials. 4 refs.

## Chemistry

**092286 REACTIVITIES OF SULFUR-CENTERED RADICAL TOWARD POLYISOPRENES AND POLYBUTADIENES STUDIED BY FLASH PHOTOLYSIS METHOD.** The kinetic behavior of the thiyl radical in the solution containing polyisoprenes and polybutadienes has been studied by the flash photolysis method. For benzothiazole-2-thiyl radical, the addition rate constants toward these polymers and the model compounds of the polymers were evaluated. The relative reverse rate constants and equilibrium constants were also estimated. The addition rate constants decrease with an increase in the degree of polymerization. The relative reverse rate constants for the polymers are smaller than those for 2-methyl-2-butene, suggesting a kind of polymer effects; i.e., it can be presumed that the bonded-thiyl radicals migrate very rapidly to the neighboring double bonds in the polymer. Significant differences in the rate parameters were observed between polyisoprene, and polybutadiene, between cis- and trans-polyisoprenes, and between 1,4- and 1,2-polybutadienes. (Edited author abstract) 24 refs.

Ito, Osamu (Tohoku Univ, Sendai, Jpn); Tamura, Saburo; Murakami, Kenkichi; Matsuda, Minoru. *J Polym Sci Part A* v 26 n 5 May 1988 p 1429-1438.

## Crack Propagation

**092287 CUT-GROWTH BEHAVIOUR OF EPDM-BROMOBUTYL RUBBER BLENDS UNDER REPEATED STRESSING.** Cut-growth behavior of ethylene-propylene-diene rubber (EPDM), bromobutyl rubber (BIIR) and their blends under dynamic loading has been studied over a range of temperatures. The crack-growth resistance increases with the increase of BIIR content in the gum and filled blends. The 30:70 EPDM:BIIR blend, however, gives the best fatigue resistance because of morphology and strain energy density factors. Failure surfaces have been examined both by photography and electron microscopic techniques. The crack always propagates from the precut. The rate of crack propagation is faster for EPDM gum samples. The blends show fracture features intermediate between those of fractured BIIR and EPDM rubbers. Straight flow lines, cracks and fatigue striations (10 to 15  $\mu$ m distance between two consecutive striations) are observed for gum samples. The flow lines are increased and the cracks are reduced for filled samples. The fractography of the crack front at the precut and that away from it are similar. At a higher temperature (100°C), there is a reduction of fatigue life for the blends and pure rubbers. Many cracks are observed on the fracture surface of gum and filled samples. (Author abstract) 11 refs.

**092288 THERMOELASTIC MEASUREMENTS OF SOME ELASTOMERS UNDER EXTENSION AND TORSION.** The relative energetic contribution to the retractive force of a deformed rubber sample,  $F_e/f$ , and the corresponding  $M_e/M$  have been evaluated from thermoelastic measurements of constant pressure. A wide range of elongations  $1.25 < \alpha < 3.0$  has been studied over the temperature range 20-100°C. Thermoelastic measurements have been obtained for butyl rubber, cis-polybutadiene rubber and styrene-butadiene rubber, using two different experimental techniques, the first from measurements of  $F_e/f$  in simple extension, and the other from measurements of the internal energy contribution  $M_e$  to the restoring couple  $M$  in cylindrical rubber samples (subjected to combined torsion about the axis and extension in the axial direction). The results of this work are used to assess the principal theories of elasticity. (Edited author abstract) 23 refs.

## Degradation

**092290 THERMOCATALYTIC DEGRADATION OF ISOBUTYLENE POLYMERS IN PRESENCE OF MAGNESIUM CHLORIDES.** The thermal degradation of polyisobutylene and butyl rubber in presence of magnesium chloride is activated by chemically bound water as is confirmed by the experimental results and quantumchemical calculations. A feature of the thermocatalytic degradation is the combination of the processes of initiation by the 'law of chance' and the 'law of end groups'. Analysis of the experimental data and the quantum chemical calculations shows that the activity of the magnesium chloride crystallohydrates in the thermal degradation of PIB is due to the presence in the catalysts of chemically bound water. (Edited author abstract) 9 refs.

**092291 KINETICS AND MECHANISM OF THE OZONE DEGRADATION OF NITRILE RUBBERS IN SOLUTION.** The kinetics of the decrease in the molecular mass of three nitrile rubber samples, containing, respectively, 20, 28 and 39 mol% of acrylonitrile, has been studied viscosymetrically during their ozonization in solution. By comparing the functional groups obtained during ozonolysis of the C=C bonds with the amount of the ozone consumed, it has been found that approximately 1 mole of ozonides or 2 moles of aldehydes are formed from 1 mole of reacted ozone. An attempt has been made to prove the authors' suggestion that the intensity of the ozone degradation in solution of polybutadiene elastomers with predominantly 1,4-trans bonded butadiene, is considerably higher than that of the 1,4-cis-polybutadiene rubbers. (Edited author abstract) 19 refs.

Anachkov, M.P. (Inst of Kinetics & Catalysis, Sofia, Bulg); Rakovsky, S.K.; Stefanova, R.V.; Shopov, D.M. *Polym Degradation Stab* v 19 n 4 1987 p 293-305.

## Dielectric Properties

**092292 DIELECTRIC PROPERTIES OF PERBUNAN RUBBER:  $\gamma$ -IRRADIATION EFFECTS.** A systematic dielectric study over a frequency range extending from 200 Hz to 100 KHz and temperature ranging from 20° to 60°C has been carried out on perbunan rubber. The acrylonitrile content of the rubber samples was 28% and 38%. The effect of 15 MR  $\gamma$ -irradiation on the dielectric properties of both samples was studied and the results are interpreted. The study revealed that NBR-38 is better than NBR-28 for insulating purposes. (Author abstract) 5 refs.

Abd El-Nour, K.N. (Nat'l Research Cent, Cairo, Egypt); Fouda, I.M.; Migahed, M.D. *Polym Degradation Stab* v 19 n 3 1987 p 207-211.

**092293 EFFECT OF THERMAL AGING ON XANTHAN SOLUTIONS.** Few investigations have been carried out to study the mechanical and electrical properties of this type of rubber. The effect of the stepwise addition of conventional rubber ingredients to raw butyl rubber on its dielectric properties was previously carried out at low frequency region. Systematic studies of the dielectric properties of butyl rubber is not yet available over a wide range of frequency. In this note, the dielectric properties are studied at a wide range of frequencies extending from  $10^6$  to  $10^{10}$  Hz. The values obtained for  $\epsilon'$  and  $\epsilon''$  for the different samples are shown graphically. The values of  $\epsilon'$  and  $\epsilon''$  increase with increase of filler content. From these figures it is clear that pure there is a region of anomalous absorption with a maximum at about  $10^7$  Hz, which corresponds to pure Debye losses. The position of the maximum is nearly the same for the filler-free sample and the filled ones, indicating that there is no chemical interaction between any of the fillers and butyl rubber. 8 refs.

## Elasticity

**092294 EXPERIMENTAL ANALYSIS OF THE MOLECULAR THEORY OF RUBBER ELASTICITY.** Stress-strain and birefringence-strain experiments, on polybutadiene and poly(methyl-3,3,3-trifluoropropyl siloxane) elastomeric networks of various degrees of crosslinking have been carried out in order to evaluate the molecular theory of rubber elasticity, which is based on the idea of constraints imposed by entangled network chains on crosslink fluctuations. Previously published results on polyoxypropylene and poly(dimethylsiloxane) networks have also been analyzed. In general, the theory describes the elastic behavior of all these systems satisfactorily. Stress-strain and birefringence data can be interpreted using the same set of parameters. (Edited author abstract) 18 refs.

**Evaluation** See RUBBER—Evaluation.

## Extrusion

**092295 COMPARISON OF SCREW EXTRUSION OF RUBBER COMPOUNDS WITH DIFFERENT EXTRUDER/SCREW COMBINATIONS.** The authors describe a fundamental study of flow mechanisms in screw extruders for rubber compounds. They expand their earlier studies based on the Maddock screw-pulling procedure, with rubber strips containing markers in a comparison of three different screw extruders. The placement of the rubber is recorded and the rubber sections examined for their flow patterns. This work also extends their earlier market experiments on flow of rubber compounds through dies. Their results on screw extruders

exhibited both transverse flow patterns and sometimes showed a starved, partially filled screw. Their efforts in this paper seek to generalize these results. They also describe a theoretical model for the flow of rubber compounds in a screw extruder and compare it with their experiments. 28 refs.

**092296 AIR-LUBRICATED DIE FOR EXTRUSION OF RUBBER COMPOUNDS.** In many cases, the output of a rubber extruder is limited by the resistance of flow in the die. It is shown that the resistance of flow of rubber compound through the die can be greatly reduced while retaining good product appearance, by using a die with a porous wall and injecting air so as to separate the extruding rubber from the wall. This method seems to be especially suitable for extrudates of circular and annular cross sections, where the same extrudate swelling develops in all directions. 6 refs.

## Fillers

**092297 EFFECT OF SILANE COUPLING AGENT ON VULCANIZATION, NETWORK STRUCTURE, POLYMER-FILLER INTERACTION, PHYSICAL PROPERTIES AND FAILURE MODE OF MICA-FILLED STYRENE-BUTADIENE RUBBER.** Physical properties of composites from mica and styrene-butadiene rubber (SBR) have been studied with special reference to the effect of silane coupling agent (A-174) in the compound. Tensile and tear properties increase with the addition of mica. The increase of tensile properties is more pronounced in the case of silane-treated mica. Silane treatment also raises the volume fraction of rubber in solvent-swollen rubber vulcanizate. Attempts have been made to correlate the changes in properties with the network structure of rubber. In order to understand the mechanism of failure, tensile fracture surfaces have been examined by scanning electron microscopy (SEM). The fractographs have been correlated with the strength and type of failure of these composites. The observed values of viscosity (rheometric) corresponds to the calculated values from existing theory based on the hydrodynamic model of dispersed particles in a fluid medium. (Author abstract) 26 refs.

## Heat Resistance

**092298 HEAT RESISTANCE EVALUATION FOR RUBBER COMPOUNDS.** The method used for calculating heat resistance index (HRI) by studying the kinetics of elongation loss, has been shown to be a more thorough method of comparing rubber materials for hardening upon aging under accelerated conditions. The HRI analysis describes in this paper gives a more comprehensive technique for developing heat resistant materials based on different polymer systems are demonstrated by the excellent correlation between elastomeric shaft seal life and HRI. HRI may be a valuable technique for estimating service life of rubber components where heat hardening is the primary contributor to rubber failure. 12 refs.

## Injection Molding

**092299 INJECTION MOULDING OF LIQUID SILICON RUBBER.** With liquid silicone rubber (LSR) one differentiates between single and double component systems, which can be processed on injection moulding

machines with or without the addition of colour pastes. Single component systems crosslink with peroxides, in the same way as with the conventional production of mouldings in solid silicone rubber. The speed of vulcanisation is mainly determined by the peroxide used. With the two-component system the advantages of addition crosslinkage are utilised. The two-component liquid silicones differ from conventional elastomers, in that they are ready-to-use blends of paste-like consistency. That also is a reason, why the processing of liquid silicone rubbers is gaining entrance into shops specialising in thermoplastics injection moulding. Liquid silicon rubbers excel through good low-temperature flexibility, superb ageing characteristics (particularly under the influence of ozone) and distinguished dielectrical performance over a wide temperature range. 6 refs.

**092301 COMPARISON OF TENSILE AND SHEAR BEHAVIOR OF CARBON-BLACK-FILLED ELASTOMERS.** When the carbon black is compounded into rubber on a two-roll mill, an experienced operator sometimes stretches the compound by hand to see if a satisfactory dispersion of carbon black is achieved. This demonstrates that the elongational behavior is one of the important characteristics of the compound. Comparison of elongational and shear behavior is expected to yield information on the difference in behavior of the gum and the filled compound. This paper presents the results of these measurements, a systematic treatment of the data, and an interpretation based on a possible mechanism concerning the role played by carbon black on the deformation of the compound. 22 refs.

**092302 EFFECTS OF MIXING PROCEDURE ON DYNAMIC MECHANICAL PROPERTIES OF AN ETHYLENE-PROPYLENE-DIENE RUBBER/BROMOBUTYL RUBBER BLEND.** Ethylene-propylene-diene rubber (EPDM) and bromobutyl rubber (BIIR) are widely used in automotive suspension applications. In this work, the effects of mixing procedure on the dynamic mechanical properties of the EPDM/BIIR blends have been investigated using a Du Pont 1090/982 Dynamic Mechanical Analyzer. These properties include storage modulus and damping coefficient. Experimental data show that the low temperature dynamic mechanical properties of the blend compositions mixed using a constant temperature procedure are better than those mixed by a conventional method. (Edited author abstract) 7 refs.

**092303 EFFECTS OF TRANS-POLYOCTENYLENE ON THE MECHANICAL PROPERTIES OF**

**NBR.** Trans-polyoctenylene (TOR), a high-polymer polymerization product of cyclooctene, has found use as a processing aid in high-viscosity rubber stocks. The authors have compared some physical and mechanical properties of a NBR-compound with TOR with those of the same compound without TOR. Mooney viscosity was lower for the compound with TOR. Cylinders with a height and diameter of 20 mm were molded. It was found that stress-relaxation measured in the common static way was almost the same for the two compounds. Dynamic stress-relaxation occurred much more rapidly for the compound with TOR. The compound with TOR increased in hardness more rapidly when aged in air, and showed a higher swelling in oil. The DSC results imply that TOR is incorporated as a separate phase in the parent rubber. The sealing properties are affected detrimentally when TOR is used as a processing aid in NBR. (Edited author abstract) 6 refs.

**092304 EFFECT OF FLAW SIZE ON TENSILE RUPTURE AND MORPHOLOGY OF FRACTURE SURFACE OF SYNTHETIC RUBBERS WITH SPECIAL REFERENCE TO ROCKET INSULATOR COMPOUND.** Studies on tensile strength of polybutadiene (RR) and ethylene-propylene diene rubber (EPDM) having a wide range of flaw sizes have been carried out under both normal and aging conditions. A similar study has been done for a solid propellant rocket insulator compound, based on EPDM. The morphology of tensile fracture surface has also been reported in each case in order to understand the mechanism of rupture. Unlike NR, EPDM, and BR gum vulcanizates, both unaged and aged, show no critical cut length ( $l_c$ ). Scanning electron microscopic studies show that the mechanism of rupture EPDM and BR gum vulcanizates are similar throughout the whole range of precuts. It occurs through a tearing process originated from the given precut at the center of the samples. A quantitative relation between tensile strength and distance between crack lines/tear lines has also been found. Though insulator compound shows a definite  $l_c$ , similar fracture surface has been observed over the entire range of flaw sizes. (Edited author abstract) 6 refs.

**092305 TENSILE IMPACT AND FLEX FATIGUE FAILURE OF EPDM/XLPE BLENDS.** The impact strength increases with the weight per cent of XLPE and reaches a maximum at 70 percent XLPE. The tensile strength increases at lower proportions of XLPE and tends to level off at higher ( $\geq 70$  percent) proportions. The impact behaviour can be correlated with the increase in tensile strength which increases the force required to rupture the specimen and prevents the crazes from developing into a crack. As the proportion of XLPE increases, the flex resistance decreases and the rate of decrease is sharper at lower proportions of XLPE ( $< 50$  percent). The decrease of fatigue resistance with increase of XLPE is associated with the high stiffness of the XLPE compared to EPDM. 12 Refs.

## Microstructure

**092306 STRUCTURE AND PROPERTIES OF A NEW SYNTHETIC TIRE RUBBER: HIGH-TRANS SBR.** In 1978, the authors described a Ba-Li catalyst system capable of producing butadiene homopolymer and butadiene-styrene copolymers with trans-1,4 sequences long enough to cause crystallization and correspondingly good green strength. The present paper focuses on further development, at the author's laboratory, leading to styrene-butadiene rubbers which possess excellent green strength and tack strength. Their black vulcanizates

display outstanding abrasion resistance, are resistant to oxidation and crack initiation, and, in blends with NR, show a remarkably low rate of crack growth. 23 refs.

## Molecular Structure

**092307 DETERMINATION OF THE STRUCTURE OF CHLOROBUTYL AND BROMOBUTYL RUBBER BY NMR SPECTROSCOPY.** Chlorobutyl and bromobutyl rubbers are manufactured by adding molecular chlorine or bromine to a solution of butyl rubber in a hydrocarbon solvent. The chemical structures of the halobutyl rubbers have not been fully characterized, because the isoprenyl content, the site of the halogenation reaction, is very low (less than 3%). This paper reports the detailed  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra of both chlorobutyl and bromobutyl rubbers and assigns the observed signals to the exomethylene structure. Attempts are also made to assign minor signals in the  $^1\text{H}$  spectra to other possible structural variants. 12 refs.

## Oxidation

**092308 PHOTO-OXIDATION OF EPDM RUBBER: PART 1 - KINETICS OF OXYGEN CONSUMPTION.** In this paper we describe the kinetics of oxygen consumption of films of nonvulcanised EPDM rubber irradiated with UV light. Purified rubber shows a lower consumption rate compared with crude rubber. Also, a strong lowering of the rate is observed on irradiating at 365 nm compared with 313 nm. Introduction of benzophenone as initiator increases the rate on irradiating at 365 nm. These results are interpreted in terms of impurity initiated photo-degradation. Use of a hindered amine additive decreases the overall rate of oxygen consumption in proportion to its concentration in the films, thus acting as a stabiliser for this rubber. This stabilising effect is also observed when benzophenone is present in the film. (Author abstract). 12 Refs.

## Performance

**092309 VERHALTEN VON EPDM BEI TIEFEN TEMPERATUREN.** [Low-Temperature Behavior of EPDM]. The low-temperature performance of technical rubber goods is increasingly being specified with respect to compression set, hardness and torsion modulus. Using ethylene-propylene rubber, the author investigates to what degree molecular structure, molecular weight and tercomponent influence the behavior of vulcanisates at low temperature. Beside the rubber, lubricants and plasticisers affect the flexibility as well, as demonstrated by comparing a mineral oil that has a solidification point above the glass transition temperature of the rubber with an ester plasticiser whose solidification point lies below the  $T_g$  of the rubber. (Edited author abstract) In German.

Mahlke, D. *Kautsch Gummi Kunstst* v 40 n 10 Oct 1987 p 931-934.

## Physical Properties See Also LIGNIN; RUBBER—Physical Properties.

**092310 ETHYLEN-ACRYLATAUTSCHUK - EIN KOSTENGUNSTIGER DICHTUNGSWERKSTOFF FUER HOHE BEANSPRUCHUNGEN.** [Ethylene-Acrylate Rubber - a Cost-Profitable Temperature Resistant Sealing Material]. This paper describes the development of ethylene-acrylate rubber Vamac (Du Pont) and its use as temperature resistant sealing material. The compound is explained and the physical properties of respective vulcanisates, especially after long term aging at 120 and 140°C, are presented. Furthermore this work shows the

technical possibilities and the significance of this new inexpensive polymer for the manufacture of rocker cover seals, inner axle boots for the automotive industry and oil hose covers in comparison with conventional sealing materials, like NBR and ACM. (Edited author abstract) In German.

Huebsch, D. *Kautsch Gummi Kunstst* v 41 n 3 Mar 1988 p 239-241.

## Polymerization

**092311 EFFECT OF CHEMICAL MODIFICATION OF SOLUTION-POLYMERIZED RUBBER ON DYNAMIC MECHANICAL PROPERTIES IN CARBON-BLACK-FILLED VULCANIZATES.** The above-mentioned chemical modification has been developed by slightly modifying the chain-ends using a lithium catalyst system without changing the main chain structure. The chemical modification involves an addition reaction of some polar compounds such as EAB [4,4'-bis-(diethyl amino)benzophenone]. The chemical modification has been applied to both high-vinyl polybutadiene (Nipol BR 1245) and solution-polymerized SBR (Nipol SBR NS 110's). Characteristics of the modified rubbers as compared with unmodified rubbers are the improved rebound resilience (hence low rolling resistance) without sacrificing wet-skid resistance. The purpose of this paper is to clarify the mechanism of the improvement by the chemical modification. 15 refs.

## Processing See Also RUBBER.

**092312 EFFECT OF MOULDING PRESSURE, COOLING RATE AND CURING TEMPERATURE ON THE PROPERTIES OF ROCKET INSULATOR.** A new solid propellant rocket insulator compound based on ethylene-propylene diene rubber (EPDM) meets all the technical properties needed for the purpose. In order to have a field trial of the compound, the effect of molding pressure, cooling rate and curing temperature on the technical and swelling properties has been investigated and the results are reported. Molding of the insulator compound at high pressure, low cure temperature and slow cooling rate gives the maximum values of physical properties and the minimum swelling. The density of the compound, however, increases. All the changes in properties are explained on the basis of rubber-filler interaction. 4 refs.

**092313 PROCESSABILITY OF EPDM RUBBERS IN INTERNAL MIXERS - DEPENDENCE ON MOLECULAR STRUCTURE.** For a number of EPDM grades differing in molecular structure and molar mass distribution, the authors investigated the carbon black dispersion rate during mixing in a three-liter internal mixer. They used an average EPDM compound composition with 70 phr FEF black, 40 phr SRF black and 70 phr naphthenic oil. Depending on the instantaneous temperature of the compound, the mixing process in an internal mixer can be divided into several stages, using the analogy of the different regimes in the behavior of pure rubber on a two-roll mill. (Edited author abstract). 14 Refs.

**092314 FOAMING CHARACTERISTICS OF FILLED SOLUTIONS OF NITRILE BUTADIENE RUBBER.** During the development of nitrile-butadiene-rubber-based coatings, persistent foaming - a grave obstacle in such applications - was encountered. An investigation was undertaken to study the behavior of foams in order to prevent their formation. Both the

apparent viscosity and the foam stability were found to attain their minimum values at the same filler level. It is plausible that the observed phenomenon is due to the binding of polymer chains to filler particles, which takes place most effectively at a certain proportion of filler and polymer. (Author abstract). 9 Refs.

## Research

**092315 SILICONE RUBBER, ITS DEVELOPMENT AND TECHNOLOGY PROGRESS.** This paper discusses the development and technological progress of silicone rubber since it first became commercially available within the U.S. in 1944 from both the Dow Corning Corporation and the General Electric Company. Advances in silicone rubber have been brought about by the need to satisfy practical market place requirements not fulfilled by other elastomers, and certainly not least in importance, by the scientific challenge to improve technology. Fundamentally involved in the use of silicone rubber in fulfillment of market needs is the combination of the performance properties that silicone rubbers exhibit. These properties include excellent weather and thermal stability, ozone and oxidation resistance, good electrical properties, extreme low-temperature flexibility, low activation energy for viscous flow, high gas permeability, good release from organic materials, good solvent and oil resistance, physiological inertness (compatible with body tissue), and being curable by a variety of methods at both elevated and ambient temperatures. 33 Refs.

Polmanteer, Keith E. (Dow Corning Corp, Midland, MI, USA). *Rubber Chem Technol* v 61 n 3 Jul-Aug 1988 p 470-502.

## Rheology

**092316 TEMPERATURE-PRESSURE INDUCED RUBBER-CARBON BLACK INTERACTION IN UNCURED RUBBER COMPOUNDS.** When assessing the viscosity of rubber-carbon black masterbatches versus temperature, peculiar variations with heat input were observed, using either capillary or rotational rheometers. These anomalies can be explained by the formation of a pseudo-structure induced by the temperature and the bulk pressure conditions within the instrument cavity. Extensive tests were carried out on NR and SBR compounds containing carbon blacks with various structures and particle sizes; the results obtained show that the pseudo-structure formation is enhanced by the surface activity of the filler. Experimental results support the hypothesis that variations in the amount of occluded rubber rather than in the volume of bound rubber are involved in these effects. (Edited author abstract) 6 refs.

Leblanc, J.L.; Swiderski, Z. *Kautsch Gummi Kunstst* v 40 n 9 Sep 1987 p 815-819.

## Spectroscopic Analysis

**092317 ANALYSIS OF NITRILIC RUBBER VULCANIZATES.** Analysis of the acrylonitrile content (AN) in NBR vulcanizates faces the difficulties encountered with elastomers with a heteroatom in their molecule. In this investigation, identification and quantitative analysis of NBR vulcanizates and NBR/PVC composites were done applying TG, DTG and IR techniques. Glass transition temperature ( $T_g$ ) was determined from loss factor ( $\tan \delta$ )/temperature graphs. Glass transition temperature was found to increase the AN content in NBR. (Author abstract) 7 refs.

#### Stresses See Also RUBBER—Stresses.

**092319 EFFECT OF CROSS-LINKS WHICH OCCUR DURING CONTINUOUS CHEMICAL STRESS-RELAXATION.** Large radiation-induced stress increases observed during the continuous stress-relaxation of a nitrile rubber aged in an inert,  $\gamma$ -radiation environment are analyzed using a simple (no adjustable parameters) shrinkage model derived from linear viscoelasticity. Stress-relaxation experiments based on the model in conjunction with determination of the time-dependence of the material's modulus and linear shrinkage show that the observed increases in stress can be quantitatively accounted for by shrinkage effects caused by new cross-links. In contrast to typical assumption, the results therefore show that new chemical cross-links formed during continuous stress-relaxation studies can have a large impact on the relaxation results. By using the model in conjunction with stress-relaxation conducted as a function of initial sample strain, estimates can be made of the importance of shrinkage effects for any elastomer. (Author abstract) 9 refs.

Gillen, Kenneth T. (Sandia Natl Lab, Albuquerque, NM, USA). *Macromolecules* v 21 n 2 Feb 1988 p 442-446.

#### Synthesis

**092320 USE OF THE UNIFAC METHOD FOR EQUILIBRIUM CALCULATIONS IN SYSTEMS WITH HETEROCYCLIC OXYGEN-CONTAINING COMPOUNDS.** The authors used the UNIFAC method for calculation of liquid-vapor equilibria in systems studied previously, containing 4,4-dimethyl-1,3-dioxane (DMD), MDHP, and MTHP. Owing to absence of literature data on group-interaction parameters of the  $-CH_2O-$  group in the pyran and dioxane rings, the calculations were performed in two variants, with parameters of the  $-CH_2O-$  ether group, and with parameters of this group in the tetrahydrofuran series. The results of calculations relating to systems studied in the literature are given. It is shown that the use of the  $-CH_2O-$  group in the tetrahydrofuran series raises the accuracy of prediction both of the composition and of the boiling points of the mixture. In view of the practical importance of systems with heterocyclic compounds, it was necessary to obtain corrected parameters of group interaction for groups in the molecules of the heterocyclic compounds. Accordingly, we calculated group-interaction parameters for the  $-CH_2O-$  group in the dioxane and pyran rings from available literature data, using the UNIEX program. The averaged results of these calculations are given. This work is pertinent to synthetic rubber synthesis. 8 refs.

#### Thermal Effects

**092321 SPECTROSCOPIC STUDIES ON THE INITIAL STAGES OF THERMAL DEGRADATION OF POLYCHLOROPRENE.** Thermal degradation of polychloroprene under nitrogen, especially at the initial stages, has been studied by using  $^1H$ -NMR,  $^{13}C$ -NMR and FT-IR spectroscopy. A model polymer of low molecular weight was prepared to avoid gelation during degradation. None of isomerized 1,2 unit has been found in the original polymer. Allylic rearrangement of 1,2 unit was the

first-stage reaction, which was finished within 30 min at 150°C. The extent of HCL loss was proportional to the decrease of isomerized 1,2 unit. It has been suggested that the next-stage reaction is dehydrochlorination of the isomerized 1,2 unit. (Edited author abstract) 16 Refs.

#### Thermodynamic Properties

**092322 VISCOSITY AND SOME THERMODYNAMIC PROPERTIES OF BUTYL RUBBER SOLUTIONS IN VARIOUS SOLVENTS AT LOW TEMPERATURES.** Generalized dependences of effective viscosity on shear rate and of maximum newtonian viscosity on concentration were obtained for moderately concentrated solutions of butyl rubber in various solvents and their mixtures with the monomer at temperatures from 50 to -90°. The dependences of the rheological Martin constant and of intrinsic viscosity on the composition of the solvent-monomer mixture, on temperature and on molecular mass of the rubber were obtained. Values of the thermodynamic parameters characterizing intermolecular polymer-solvent interactions were calculated, and the  $\theta$ -temperature values of the solutions and their dependence on the composition of the solvent-monomer mixture were predicted. (Author abstract) 20 refs.

#### Viscoelasticity See Also SILICA—Textures.

**092323 VISCOELASTIC CHARACTERIZATION OF LONG BRANCHING AND GEL IN ELASTOMERS BY COMPARISON OF LARGE AND SMALL DEFORMATIONAL BEHAVIOR.** Ten different raw elastomers of varied chemical structure and Mooney viscosity were characterized with both tensile stress-strain behavior and dynamic shear behavior. The room temperature tensile stress-strain behavior was determined at strain rates of 0.239, 0.0892, and 0.00653 sec<sup>-1</sup>. These stress-strain data were reduced with a use of strain-time correspondence principle. The dynamic-shear behavior was observed over the frequency range from 10<sup>-2</sup> to 10<sup>2</sup> rad/s. Double logarithmic Cole-Cole plots were used to characterize a relative degree of long branching and gel content. 22 refs.

**092327 CURE ADHESION IN THE INTERFACE OF FLUORINATED AND NITRILE RUBBERS.** Recently there has been a great deal of interest in new composite rubbery materials. Good properties require the reinforcement of the interfacial region which is formed between different rubbers. This work indicates newly developed vulcanization systems which are very effective in producing fluorinated and nitrile butadiene composite materials with very good properties, because they induce interpolymer interactions. The new systems are distinguished by the presence of common vulcanizing agents and accelerators. 27 refs.

Mori, Kunio (Iwate Univ, Morioka, Jpn). *Rubber Chem Technol* v 60 n 5 Nov-Dec 1987 p 822-836.

**092328 THERMOVULCANIZATION OF POLYCHLOROPRENE RUBBER AND ITS BLENDS WITH POLY(VINYL CHLORIDE).** Heat and mechanical stressing at higher temperature effect changes in polychloroprene rubber leading to network formation. During thermovulcanization of polychloroprene rubber in the temperature range of 150-200°C, two reactions have been observed and their kinetic parameters determined. When the rubber is stressed by shearing forces, the rate of degradation crosslinking is fairly high even at relatively low temperatures (90-150°C). Thermovulcanization of polychloroprene rubber/poly(vinyl chloride) blends has been investigated in the entire concentration range at 180°C. Maxima have been observed on the dependences of some kinetic parameters of the thermovulcanization reaction on polymer blend composition. (Author abstract) 13 refs.

#### Compression Tests

**092329 STUDY OF SPONTANEOUS RUBBER/METAL ADHESION. I. THE ROLLING CYLINDER TEST.** The spontaneous adhesion of vulcanized filled elastomers to steel has been studied using a rolling cylinder test. Owing to the relatively high degree of crosslinking, heavy cylinders are required to ensure good contact with the hard rubber track. This in turn invokes compression within the bulk of the rubber. A consequence is that hysteresis losses are associated not only with the adhesion phenomenon but also with the compression deformation of the system. Theoretical and experimental analyses have led to the conclusion that the two effects may be treated as additive. Both hysteresis losses can be related to the WLF superposition principle. (Author abstract) 13 refs.

Zaghzi, N. (Cent de Recherches sur la Physico-Chimie des Surfaces Solides, Mulhouse, Fr); Carre, A.; Shanahan, M.E.R.; Papirer, E.; Schultz, J. *J Polym Sci Part B* v 25 n 11 Nov 1987 p 2393-2402.

#### Elasticity

**092330 RUBBER TESTING WITH THE DEFO-ELASTOMER.** Rheology measurements allow to characterize rubber polymers or provide reliable quality control tests of rubber compounds. Specimens tested in a

two-plate-plastometer flow when compressed, elastically recover part of their height when the compression load has been removed. The test results provide information on viscosity, elasticity, shear rate dependency of viscosity, and fatigue. Special emphasis is placed on the method to provide perfect specimens using vacuum compaction. The Defo-Elastomer is backed by modern computerization to allow easy handling of tests, to store data and to provide the results in tabulated and graphical form. (Edited author abstract) 1 ref.

**Fatigue** See ELASTOMERS—Mechanical Properties; RUBBER—Fatigue.

## Fracture

**092331 RUBBER FRACTURE CHARACTERIZATION USING J-INTEGRAL.** The use of the J-integral to investigate fracture characterization in a carbon black reinforced natural rubber is described. Three applications to crack initiation are included: two based on the use of a hypothetical zero specimen length and one on conventional testing procedures for metals. While the validity of the zero-length methods is questionable, the conventional method yielded a consistent  $J_c$  value of 1.01 N/mm for a typical tire compound. This value was obtained from 24 combinations of varying specimen geometries and pre-crack lengths. The J-integral is revealed as a valid fracture parameter that is applicable not only for material evaluation but also for designing tire structures to resist premature failure. (Edited author abstract) 22 refs.

## Friction

**092332 DETERMINATION OF THE COEFFICIENT OF FRICTION OF RUBBER AT REALISTIC TIRE CONTACT PRESSURES.** To obtain a value of the coefficient of friction corresponding to a given pressure, as uniform a contact pressure distribution as possible should be maintained, and mechanical interference due to extraneous edges should be eliminated. An axially symmetric rotational test using an annular specimen eliminates the frictional lift phenomenon responsible for the high pressure gradients in conventional tests. This basic concept, used by Gent and Henry (1982), was modified to emphasize a uniform contact pressure distribution and high pressure applications. Therefore, a test apparatus was built to implement this concept, and the results obtained are considered to represent pointwise values of the coefficient of friction at the given normal pressure. 5 refs.

**092333 EFFECT OF CARBON BLACK ON THE J-INTEGRAL AND STRAIN ENERGY IN THE CRACK TIP REGION IN A VULCANIZED NATURAL RUBBER.** It is shown that carbon black increases the size and the energy density of the process zone, but not the local crack-tip strain at which crack initiation occurs. Thus it appears that the critical condition for crack initiation at the crack tip is strain-controlled, and CB increases the energy required to achieve this. Related studies by X-ray diffraction and differential scanning calorimetry show that CB increases the strain-induced crystallization of natural rubber in general and at the crack tip, and this is a significant sink for energy and a source of fracture resistance. 22 refs.

Liu, H. (Univ of Massachusetts at Amherst, Amherst, MA, USA); Lee, R.F.; Donovan, J.A. *Rubber Chem Technol* v 60 n 5 Nov-Dec 1987 p 893-909.

**092334 MICROSTRUCTURAL CHANGES IN THE CRACK TIP REGION OF CARBON-BLACK-FILLED NATURAL RUBBER.** This study shows that carbon black increases the amount of strain-induced crystallization (SIC) in the crack tip region, and suggests that in natural rubber this contributes significantly to crack growth resistance. It is suggested that an apparently over-looked effect of CB on the extent of crystallization, originally reported by Gehman and Field in 1941, makes a major contribution to crack initiation and rupture resistance by increasing the extent of crystallinity and increasing the size of the crystallized zone at comparable crack driving forces. SIC absorbs deformation energy in proportion to the amount of transformation; therefore CB allows more energy to be dissipated through the transformation. Hence, CB-filled rubber requires more energy to establish the critical conditions in the crack tip. 14 refs.

## Wear

**092335 SCANNING ELECTRON MICROSCOPY STUDIES ON WEAR OF HDPE-FILLED NATURAL RUBBER VULCANIZATES.** The wear properties of natural rubber (NR) vulcanizates filled with high density polyethylene (HDPE) have been studied. The mechanism of wear was explained on the basis of abraded surface morphology. It was found that incorporation of HDPE increases the abrasion resistance of NR vulcanizates and the abrasion mechanism changes from frictional wear to abrasive wear with increasing HDPE loading. (Edited author abstract) 28 refs.

## RUBIDIUM See Also LASERS, DYE—Performance.

**092336 CROSS SECTION OF THE REACTION  $^{85}\text{Rb}(\gamma, n)^{84\text{m}}\text{Rb}$ .** The cross section for the formation of isomeric states  $^{84\text{m}}\text{Rb}$  in the photoneutron reaction on the  $^{85}\text{Rb}$  nucleus was measured for the first time in this work by the method of induced activity. In previous works the isomeric ratios of the cross sections  $\sigma_m/\sigma_g$  or the yields  $Y_m/Y_g$  of this reaction were measured for energies above the energy of the gigantic dipole resonance. In this work the energy dependence of  $Y_m/Y_g$  is obtained for  $E_\gamma = 25$  MeV, with a step of  $E_\gamma = 0.5$  MeV. 11 refs.

## Isotopes

**092337 PRODUCTION OF EFFICIENT  $^{81}\text{Rb}/^{81\text{m}}\text{Kr}$  GENERATORS USING ZIRCONIUM PHOSPHATE.** Rubidium-81 is produced by bombardment of a NaBr target. The target is dissolved in water and  $^{81}\text{Rb}$  is efficiently sorbed on zirconium phosphate. Na is selectively eluted with HCl. About 80% of the  $^{81\text{m}}\text{Kr}$  can be eluted from the generator with moist air. Recoil effects and/or the relative sizes of  $\text{Rb}^+$  and  $^{81\text{m}}\text{Kr}$  may play a role in the  $^{81\text{m}}\text{Kr}$  elution efficiency. (Author abstract) 12 refs.

## Optical Pumping

**092338 SIGNAL INTENSITY VERSUS TEMPERATURE CHARACTERISTICS OF A MIXED  $^{87}\text{Rb}/^{85}\text{Rb}$  RESONANCE CELL FOR USE IN A RUBIDIUM FREQUENCY STANDARD.** The dependence of the signal intensity of the  $^{87}\text{Rb}$  microwave resonance ( $f = 6834$  MHz) on the  $^{85}\text{Rb}$  atoms included in a resonance cell

is examined about a mixed  $^{87}\text{Rb}/^{85}\text{Rb}$  cell used in an optically pumped Rb frequency standard. The temperature that gives the maximum resonance intensity in the signal intensity versus temperature characteristic curves, shifts toward higher temperatures with increasing mass ratio  $m (= ^{85}\text{Rb}/^{87}\text{Rb})$  of Rb in the cell. 17 refs.

## Radiation Effects

**092339 LIGHT-INDUCED DRIFT IN RUBIDIUM: SPECTRAL DEPENDENCE AND ISOTOPE SEPARATION.** We report on the frequency dependence of the light-induced drift velocity of rubidium in argon buffer gas. The sign of the drift velocity is found to closely follow the sign of the derivative of the low-intensity absorption spectrum. This is in disagreement with previous predictions and is qualitatively different from the sodium case. Numerical studies agree with our observations, and point to the importance of the ratio of the ground-state hyperfine splitting to the Doppler width. These observations imply that the two naturally occurring isotopes  $^{85}\text{Rb}$  and  $^{87}\text{Rb}$  can be easily separated using light-induced drift, and this is experimentally demonstrated. (Author abstract) 11 refs.

## X-Ray Analysis

**092341 PECULIARITIES OF DIRECT X-RAY DETERMINATION OF Ru, Rh AND Pd USING VEPP-4 SYNCHROTRON RADIATION.** The first results are presented of an analysis of light platinumoids (Ru, Rh, Pd) in silicate rocks, ores and references by the SRXFA technique. To improve the reproducibility of the analysis results, the sample has been scanned with a SR beam and the data obtained averaged over a large area. The influence of combinatorial lines in the SRXFA spectra, caused by the pulse nature of the radiation, has been observed. The detection limits for Ru, Rh and Pd were 0.017-0.07 ppm at a  $10^3$  s in the absence of conflicting spectral lines. (Author abstract) 5 refs.

**Electric Conductivity** See Also GLASS—Ionic Conduction.

**092342 SOME ASPECTS OF THE ELECTRICAL CONDUCTIVITY OF FERROELECTRIC RUBIDIUM HYDROGEN TARTRATE SINGLE CRYSTALS.** In this letter authors report on the growth of single crystals of RHT from solution and measurements of their electrical conductivities at different temperatures. An attempt has been made to understand the mechanism of charge transport. The following conclusions may be drawn from this study. RHT single crystals up to  $16 \text{ mm} \times 5 \text{ mm} \times 4 \text{ mm}$  in size were grown using the gel technique. They belong to the orthorhombic system and having space group  $P2_12_1$ . The variation in d.c. conductivity of single crystal and pellet samples was studied in the temperature range between 300 to 470 K. The electrical conductivity of the crystalline sample is larger than that of pellet samples. The electrical conductivity in the case of RHT crystals is intrinsic above 393 K and extrinsic below 393 K. The extrinsic conductivity is dominated by  $(\text{Rb})^+$  and  $(\text{HCOOH})_2^-$  ion impurities while the intrinsic conductivity is due to Frenkel defects. The activation energy for the electrical conduction process is estimated. The activation energy for crystals is higher than that of pellet samples. 8 refs.

Desai, C.C. (Sardar Patel Univ, Vallabh Vidyanagar, India); Patel, A.H. *J Mater Sci Lett* v 6 n 9 Sep 1987 p 1066-1068.

**092343 POLARITY STUDY OF RUBIDIUM ACID PHTHALATE (RAP) SINGLE CRYSTALS.** The pyroelectric properties related to the polarity including pyroelectric effect, dielectric property and DC-conductivities of rubidium acid phthalate (RAP) crystal have been studied in this paper. By using differential temperature analysis (DTA) and weight loss analysis, a qualitative explanation has been given on the temperature dependence of high-temperature thermoelectricity. The positron annihilation technique (PAT) is used to determine successfully the negative single vacancy distribution in the positive and negative directions of polar axis. Our experiment verifies that the DC-conductivities of RAP crystals are caused by the thermal-defect in the crystal. (Author abstract) 8 refs. In Chinese.

**Ionic Conduction** See Also POTASSIUM COMPOUNDS—Ionic Conduction.

**092345 ELECTRICAL RESPONSE OF  $\text{RbAg}_4\text{I}_5$  /GRAPHITE INHOMOGENEOUS INTERFACES.** The ac impedance of the cell graphite/graphite+ $\text{RbAg}_4\text{I}_5$ / $\text{RbAg}_4\text{I}_5$ /graphite+ $\text{RbAg}_4\text{I}_5$ /graphite was investigated in the frequency range from  $10^{-4}$  to  $3 \times 10^5 \text{ Hz}$ . A model assuming the graphite+ $\text{RbAg}_4\text{I}_5$  mixture to represent a porous interface could explain the observed dependences in nearly the whole frequency range with the exception of the lowest frequencies. Attempts to improve the agreement presuming adsorption, discharge of charge carriers or diffusion of neutral species failed. An excellent

fit could be achieved assuming a frequency dependent ac conductivity of the interface, approximately proportional to the frequency, as in the bulk of many solids with low conductivity, such as amorphous semiconductors or dielectrics. (Author abstract) 30 refs.

## Magnetic Properties

**092346 ELECTRON SPIN RESONANCE IN HYDROGENATED  $\text{RbFeSe}_2$ .**  $\text{RbFeSe}_2$  is a member of the alkali dithioferate series of compounds. A magnetic phase transition was observed at  $T_c=185 \text{ K}$ . In this letter we report ESR measurements in hydrogenated  $\text{RbFeSe}_2$  between 160 and 360 K. From the difference between two curves in the temperature range 160 to 200 K and the value of the transition temperature in non-hydrogenated  $\text{RbFeSe}_2$ , the transition temperature of hydrogenated  $\text{RbFeSe}_2$  is estimated to be approximately 245 K. Hydrogenation thus increases the transition temperature of  $\text{RbFeSe}_2$  by about 60 K. 9 refs.

de Biasi, R.S. (Inst Militar de Engenharia, Rio de Janeiro, Brazil); Taft, C.A.; Furtado, N.C. *J Mater Sci Lett* v 6 n 10 Oct 1987 p 1185-1186.

## Pressure Effects

**092349 HYDROSTATIC PRESSURE DEPENDENCE ON THE TUNNELING SPLITTING IN  $\text{RbCl}:\text{Ag}^+$ .** We present measurements of the pressure dependence of the tunneling splitting in  $\text{RbCl}:\text{Ag}^+$  for hydrostatic pressures from 950 to 1850 bar. The dependence is linear above 1100 bar and appears to have a break in the curve between 1000 and 1100 bar. This data suggests that a configurational change may take place near 1000 bar. (Author abstract) 9 refs.

Morgan, Michael (Univ of California at Santa Cruz, Santa Cruz, CA, USA); Bridges, Frank. *Solid State Commun* v 61 n 6 Feb 1987 p 355-356.

## Radiation Effects

**092350 ELECTRON-INDUCED DECOMPOSITION OF RUBIDIUM CHROMIUM FLUORIDE.** The decomposition of  $\text{Rb}_x\text{CrF}_3$  hexagonal tungsten bronzes (HTB) with  $x=0.20$  and  $0.30$  have been followed by high resolution electron microscopy (HREM). In the electron beam of the microscope, Rb is depleted from the tunnels of the bronze structure leading to the formation of  $\text{CrF}_3$  which crystallizes in a distorted  $\text{ReO}_3$ -type structure. An amorphous phase is frequently intermediate to this transformation. A qualitative comparison of the rate of reaction, depending upon the energy and direction of the electrons, of the compounds of different composition is made. These observations suggest a mechanism for the reaction. (Author abstract) 9 refs.

## High Pressure Effects

**092356 X-RAY DIFFRACTION OF RUBY ( $Al_2O_3$ ;  $Cr^{3+}$ ) TO 175 GPa.** Compression data for ruby ( $Al_2O_3$ ,  $\approx 0.05\% Cr^{3+}$ ) have been obtained by energy-dispersive X-ray scattering in a diamond-anvil cell to 175 GPa (1.75 Mbar) at room temperature. Ruby does not undergo any reconstructive structural transition to at least 175 GPa at room temperature, although there is comparatively large uncertainty in pressure due to the weakening and broadening of  $R_1-R_2$  luminescence under nonhydrostatic compression. The unit-cell volume measured at the highest pressure (where  $V/V_0 = 0.71$ ) is consistent with the predictions of a Birch-Murnaghan equation of state with parameters obtained from low-pressure ultrasonic and single-crystal compression measurements. (Edited author abstract) 27 refs.

## Impurities

**092357 CHROMIUM-GALLIUM COMPLEXES IN  $Al_2O_3$ : I. LUMINESCENCE.** The shift and broadening of the R lines in chromium-doped ruby are studied of the gallium impurity content ( $<2\%$ ). A great number of well-resolved emission lines are assigned to gallium-chromium pairs; their first and second excited states are identified by excitation spectroscopy. Weaker lines are assigned to triads formed by one chromium ion and two gallium ions. For most of these triads the shifts of the R lines due to each of the two gallium ions add linearly. A triad formed by two chromium ions (4th NN) and one gallium ion (1st NN to one chromium ion) is also identified and studied. Time-resolved fluorescence line narrowing measurements allow the determination of the energy level scheme of a pair of loosely bound chromium ions. (Author abstract) 17 refs.

Wasiela, A. (CNRS, St. Martin d'Heres, Fr); Merle D'Aubigne, Y.; Block, D. *J Lumin* v 36 n 1 Oct 1987 p 11-22.

**092358 CHROMIUM-GALLIUM COMPLEXES IN  $Al_2O_3$ : II. ENERGY TRANSFER.** In gallium-doped ruby the spectral dependence of the transfer efficiency

from isolated chromium ions to chromium-chromium pairs is very similar to that observed in gallium-free ruby, and shows no evidence for a mobility edge. The efficiency of the transfer to gallium-chromium pairs exhibits two maxima for excitation in the wings of the  $R_1$  line, an effect attributed to a non-uniform distribution of the donor-acceptor distances for such an excitation. The single-ion to gallium-chromium pair transfer is analyzed assuming a direct transfer, slightly enhanced by radiation trapping and donor-donor transfer in the samples with the largest donor concentrations. The dipole-dipole interaction deduced from the oscillator strength of the  $R_1$  line cannot account for the observed transfer efficiency. The dynamics of the acceptor emission and the transfer efficiency can be accounted for assuming either a multipolar interaction of higher order or an exchange interaction. The comparison of the observed transfer efficiency with values calculated using theoretical estimates of the quadrupole-quadrupole and exchange interactions are in favor of the latter. (Author abstract) 21 refs.

## Magnetic Field Effects

**092359 INVERSION CHARACTERISTICS OF RUBY AT THE CENTER OF THE MILLIMETER BAND.** The probabilities of spin-lattice relaxation transition in ruby for  $\theta=90^\circ$  in the range of magnetic fields 1.5-2.2 T and in the temperature range 1-5°K are calculated based on the Kroenig-Van Vleck mechanism. Different schemes for obtaining inversion are analyzed. The inversion coefficients for three and four-level pumping schemes in the frequency range 40-60 GHz are calculated. The results of experimental studies of the inversion coefficients at a frequency of 43 GHz are presented. The advantages of schemes with two-level pumping over the symmetric scheme are shown. (Author abstract) 4 refs.

## Microscopic Examination

**092360 SURFACE FACETTING AND POLARITY OF ALUMINA.** Atomic-resolution electron microscopic images of ruby show (0001) polar surface facets developing under electron irradiation. Attempts to understand the 'dark-line' contrasts associated with the surface atom profiles, following comparison of the experimental images with computer modeling, leads to the realization that aluminum atom and oxygen atom surface terminations may be distinguished. Hence surface polarity, as well as details of surface step structure and mobility, may be determined. Positive surface polarity is preferred. (Author abstract) 16 refs.

## Spectroscopic Analysis

**092363 STUDY OF TIME-DELAYED FOUR-WAVE MIXING WITH INCOHERENT LIGHT IN THE ABSORPTION BAND OF RUBY.** Time-delayed four-wave mixing with incoherent light in the absorption band  $^4T_2$  of ruby has been studied experimentally. Dephasing times have been obtained formally by analyzing the experimental data on the basis of two-level theory at different conditions. Two-level theory fails in the interpretation of the results, and a theory based on a multi-level model has been developed and applied to explain the results successfully. It is shown that  $T_2$  determined on the basis of two-level theory is not the ordinary dephasing time of individual transition but an effective one which reflects the behavior of the total absorption spectrum of the band. (Author abstract). 9 refs.

**092364 SUSPENDED SEDIMENT AND METALS REMOVAL FROM URBAN RUNOFF BY A SMALL LAKE.** A small lake in the Chicago Metropolitan Area was from 91 to 95 percent efficient in removing suspended sediment and from 76 to 94 percent efficient in removing copper, iron, lead, and zinc from urban runoff. Sediments accumulated in the lake in the form of an organic-rich mud at an average rate of 20 millimeters per year; this reduced lake storage and covered potential habitat for aquatic organisms. Copper, lead, and zinc concentrations were closely associated with suspended-sediment concentrations and with silt- and clay-sized fractions of lake sediment. Although concentrations of mercury and cadmium were near detection limits in runoff, measurable concentrations of these metals accumulated in the lake sediments. (Author abstract) 21 refs.

**092365 EFFECTS OF PRECIPITATION AND LAND USE ON STORM RUNOFF.** Storm-runoff quantity and quality were studied in three watersheds located near St. Paul in Ramsey County, Minnesota, from April 15 through September 15 of 1984, 1985, and 1986 to qualitatively determine the effects of precipitation and selected land uses on storm runoff. In respect to precipitation effects, differences in storm-runoff quantity between years in an urban watershed that lacks wetlands appear to be related to the average storm size (amount of precipitation) during the study period of each year. In contrast, the differences in storm-runoff quantity from watersheds that contain wetlands appear to be related to total precipitation during study period of each year. In respect to land use, the differences in storm-runoff quantity appear to be related to the amounts of impervious and wetland area. The watershed that contains the largest amount of

impervious area and smallest amount of wetland area has the largest amount of storm runoff. (Edited author abstract) 18 refs.

**092366 SNOWMELT RUNOFF IN SUBURBAN ENVIRONMENTS.** The runoff responses of two subcatchments of a small drainage basin in Peterborough, Ontario were investigated for the spring snowmelts of 1984 and 1985. One of the catchments has undergone substantial suburbanization, while the other is largely in rural land use. Suburban development appears to have produced substantial increases in spring quickflow yields from the entire basin. A comparison of the responses of the two subcatchments reveals that the suburban catchment reacts more rapidly to snowmelt and rain-on-snow inputs and generates larger initial quickflow response ratios than the rural basin as a result of the microclimatic, pedologic and hydraulic characteristics of build-up areas. However, the dynamic behavior of the runoff contributing area of the rural catchment results in a marked increase in its quickflow yield as melt progresses. (Edited author abstract) 34 refs.

**092367 RUNOFF GENERATION IN A PLOUGH-DRAINED PEAT BOG IN SOUTHERN SCOTLAND.** This paper reports on a study, using runoff plots and other equipment, of runoff generation in a peat bog in Scotland four years after it had been plough-drained for afforestation. In generally dry periods runoff responses were dominated by flow generated by rain falling directly onto the ditches. Only during very wet periods was this source of runoff less important than water draining into the ditches from the strips on either side. Flow from the strips to the ditches consisted entirely of groundwater. This occurred at a very low rate unless the water table was within 6-7 cm of the surface; then it could become as rapid as the rate at which rain landed on the area. The results emphasize the need to consider the ditches and the strips between them separately when seeking an understanding of runoff generation in densely plough-drained peatlands. **092368 NACHWEISE ZUR REGENWASSER-BEHANDLUNG.** [Analysis of the Treatment of Stormwater Runoff]. The analysis of the impact of stormwater runoff in combined systems is mostly limited to the evaluation of the over-flowing portion of the water. Accounting the frequency and the duration of discharges the effect of stormwater outlets may be calculated more correctly. However a general evaluation is only reasonable if also the operation and construction of the outlet and the quality of the receiving water as well as economics are considered. (Author abstract) 9 refs. In German.

**092369 MODIFIED FICKIAN MODEL FOR SOLUTE UPTAKE BY RUNOFF.** A one-dimensional Fickian diffusion model for entrainment of interstitial soil water by overland flow is modified to account for early non-Fickian mass transfer observed during laboratory runoff experiments. Results show that this asymptotic diffusion coefficient varies with the square of the quantity  $V_0/\sqrt{k}$ , where  $V_0$  is shear velocity and  $k$  is media permeability. Modifying the model entails the development of type curves for a range of convective time scales, or times of non-Fickian mass transfer. The entrainment, or mass transfer, coefficient is estimated as a function of the convective time scale. This procedure shows that the entrainment coefficient varies linearly with  $V_0/\sqrt{k}$ . Reasonable prediction of mass loss results using the asymptotic diffusion coefficients, an empirical relationship for the entrainment coefficient, and a convective time scale of 5 min as model input. (Edited author abstract). 20 Refs.

**092370 ENHANCEMENT OF RUNOFF FROM A SMALL WATERSHED BY CLOUD SEEDING.** Daily volumes of runoff, from a small watershed, are compared, with respect to daily depths of precipitation, under randomly allocated cloud seeding. Enhancement is found with respect to rainfalls at the control and at the target area. The effect is evident by doubling the number of runoff days, by doubling the ratio to the volume of the precipitation, and by heightening the regression line for nonleading days in runoff sequences. With respect to the rainfall at the control, this heightening is about 40% of the mean volume per runoff day. The generation of the runoff is governed by the abstractions which consume 98% of the precipitated waters. High rates of enhancement are found for the intense fraction of the rainfall, for the Eastern sector of the watershed and for the later portion of the rainy season. (Edited author abstract). 8 Refs.

**092371 SNOWMELT RUNOFF PATHWAYS IN A BOREAL FOREST HILLSLOPE, THE ROLE OF PIPE THROUGHFLOW.** On an instrumented slope of the Lac Laflamme basin, it was observed that, during snowmelt season: (1) the unsaturated matrix flow seems to be a negligible component of the downslope flow through the soil horizons; (2) the groundwater flow from an aquifer in till, a few meters thick, is the major pathway for rain-melt inputs; and (3) when groundwater levels are high, a turbulent pipe throughflow occurs at the mineral and organic soils interface. Gauging one of the subsurface streams showed that, although its discharge is correlated and synchronized with nearby groundwater levels, its hydrograph often reflected that of rain-melt input. Pipe throughflow does not carry more than one fifth of the seasonal rain-melt input. The water delivered by pipe throughflow forms a distinct 0.5-1 m thick acidic layer that invades the lake just beneath the lake ice cover and is susceptible to affect the fish spawning ground. **092372 FREQUENCY ANALYSIS OF ANNUAL RUNOFF FOR SMALL WATERSHEDS IN UPPER DAMODAR VALLEY.** Attempts have been made in this paper to apply the theory of probability functions to carry out the frequency analysis of the annual runoff data for twenty small watersheds in upper Damodar valley. Five probability distributions have been compared, making use of chi-square methods of goodness of fit and the magnitudes of runoff have been estimated using the best fit probability distribution for each of the watersheds at different probability levels. **092373 PATTERNS OF WATERSHED MONTHLY RUNOFF.** Two dimensional sliding polynomials were adapted to pattern analysis of watershed monthly rainfall and runoff. Contours of runoff in the two-dimensional space of time and rainfall are constructed on a grid of 16 nodes whose values are determined by least squares. This method is form free, hence derived patterns are not biased to selected functional forms, but can directly represent the smoothed data. Values of the nodes are localized averages of the data constrained by required mathematical continuity across the grid of values. An advantage of the method is that the standard deviation can be calculated for each node, thus producing patterns of uncertainty of the

deterministic component revealed by the data. (Author abstract) 16 refs.

**092374 RUNOFF GENERATION IN A LOW ARCTIC DRAINAGE BASIN.** The production of runoff from a small drainage basin in the continuous permafrost area of continental Canada was studied for two years. The basin comprises two main land types (dry tundra slopes and valley bottom wetlands) and several lakes. In spring, meltwater from most parts of the basin contributed to total runoff but the magnitude and timing of slope and wetland runoff differed. In summer this difference in runoff production was more marked. In both seasons the base of the slopes initiated runoff, which increased significantly once the wetlands began to discharge. The combined runoff mechanisms of the two land types and the linkages between them provide a general framework for an understanding of runoff generation in low Arctic basins. **092375 ESTIMATION OF THE TIME OF CONCENTRATION FOR DIVERGING SURFACES.** A solution is obtained for estimating the time of concentration for a diverging watershed. A comparison of concentration times for diverging and plane surface is made to examine the influence of the degree of divergence for a diverging watershed on the time of concentration. Assuming that the physical characteristics such as watershed length, slope, roughness and rainfall excess are the same, an expression of the ratio of the time of concentration for a diverging surface to that for a plane surface is derived. The expression is solved numerically, and evaluated graphically. (Edited author abstract). 9 Refs.

**092376 DRAINAGE BASIN PEAK DISCHARGE RATING CURVE.** The stream gauge rating curve for a drainage basin can be transformed into a drainage basin peak discharge rating curve that is more stable than the rating curve from which it is derived. The resulting drainage basin peak discharge rating curve can be used to predict peak discharge, identify anomalous discharges caused by channel obstructions or other causes, evaluate the effect of flood retarding structures, and evaluate historical records. The drainage basin peak discharge rating curve is valid for drainage basins of any size, for any discharge up to the time of concentration, and for snowmelt. (Author abstract). 6 Refs.

Rogers, Wilbur F.; Singh, Vijay P. *Hydrol Processes* v 2 n 3 Jul-Sep 1988 p 245-253.

**092377 HILLSLOPE RUNOFF PROCESSES AND MODELS.** Hillslope hydrology is concerned with the partition of precipitation as it passes through the vegetation and soil between overland flow and subsurface flow. In the 1960s and 1970s, hillslope hydrology developed as a distinct topic through the application of new field observations to develop a generation of physically based forecasting models. Some recent models have generally attempted to simplify the processes acting, for example including only vertical unsaturated flow and lateral saturated flows. Others explicitly forecast partial or contributing areas. With hindsight, the most complete and distributed models have generally shown little forecasting advantage over simpler approaches, perhaps trending towards reliable models which can run on desk top microcomputers. The variety now being recognised in hillslope hydrological response should also lead to models which take account of more complex interactions. (Edited author abstract). 60 Refs.

## Chemical Analysis See Also GEOCHEMISTRY—Groundwater.

**092379 CONTRIBUTIONS OF RAINFALL TO CONSTITUENT LOADS IN STORM RUNOFF FROM URBAN CATCHMENTS.** Rainfall is a significant source of some constituents, particularly nitrogen species, in storm runoff from urban catchments. Median contributions of rainfall to storm runoff loads of 12 constituents from 31 urban catchments, representing eight geographic locations within the United States, ranged from 2 percent for suspended solids to 74 percent for total nitrite plus nitrate nitrogen. The median contribution of total nitrogen in rainfall to runoff loads was 41 percent. Median contributions of total-recoverable lead in rainfall to runoff loads varied by as much as an order of magnitude between catchments in the same geographic location. This indicates that average estimates of rainfall contributions to constituent loading in storm runoff may not be suitable in studies requiring accurate constituent mass-balance computations. (Author abstract) 3 refs.

**092380 TOXICITY AND CHEMICAL COMPOSITION OF URBAN STORMWATER RUNOFF.** The effects of land use on the chemical composition of urban stormwater runoff and its subsequent acute toxicity to the aquatic invertebrate *Daphnia pulex* have been investigated in the Brunette drainage basin of Burnaby, British Columbia. Both land use and interval between rainfall events influenced the chemical composition and toxicity of the stormwater. The industrial and commercial land use sites were the major source of those trace metals most often considered toxic to aquatic invertebrates, with runoff from the commercial sites proving most frequently toxic to the test organism. Toxicity followed the sequence commercial > industrial > residential > open space. A detailed study of a single storm event indicated that while the 'first-flush' of the storm contributed to toxicity - through the physical scouring of insoluble pollutants - some soluble pollutants, which were washed out of the watershed later in the storm event, also proved to be toxic. Additional aspects of the subject are discussed. (Edited author abstract) 40 refs.

Hall, Ken J. (Univ of British Columbia, Vancouver, BC, Can); Anderson, Bruce C. *Can J Civ Eng* v 15 n 1 Feb 1988 p 98-106.

**092381 STREAM NITRATE LEVELS IN A SMALL CATCHMENT IN SOUTH WEST ENGLAND OVER A PERIOD OF 15 YEARS (1970-1985).** Stream nitrate levels in a small catchment of mixed land use (the Slapton Wood catchment) have been studied since September 1970; a record of this length is possibly unique in the United Kingdom for such a small basin (94 ha). A sustained increase in nitrate concentration has been observed during the study period. In addition to this long-term trend, short-term changes in nitrate concentrations relate to stream discharge levels and to seasonal variations. Multivariate statistical analysis has been used to quantify these trends and to identify those factors controlling the production and loss of nitrate from the catchment system. The main period of nitrate removal occurs in winter when high concentrations coincide with

the main period of throughflow generation. The influence of climatic variability is illustrated by reference to the 1975/76 drought and post-drought period. (Author abstract). 27 Refs.

## Components

**092382 ANALYSIS OF RUNOFF BY FREQUENCY RESPONSE METHOD.** The existence of dead time and delay time is recognized in one-component input-output system response. These two effects should not be regarded as identical. Various reports have been given on delay time over a long time as an important concept of dead time, and of runoff component separations by means of the frequency response method. The proposed method is of practical use to clarify the runoff properties. The effectiveness of the model is verified using simulated data as well as actual flood events. (Author abstract) In Japanese. 13 refs.

Saga, Hiroshi. *Doboku Gakkai Rombun-Hokokushu* v 9 n 5 May 1988 p 77-86.

## Computer Simulation See Also HYDROLOGY—Mathematical Models; MILITARY ENGINEERING.

**092383 STORM WATER SIMULATION: MODELING AND ANALYSIS OF A THREE-DIMENSIONAL CLOUD.** A simulation of storm water is presented for developing a physical understanding of storm runoff from urban basins. A new three-dimensional cloud model simulates storm rainfall. The model contains nine prognostic equations: three momentum equations, pressure and thermodynamic equations, three moisture and water equations, and a subgrid kinetic energy equation. A particular coordinate transformation is used. It maps a simulation domain with an irregular lower boundary onto a rectangular domain. A finite difference scheme which conserves heat, moisture, water substances, and subgrid-scale motion solves the transformed equations. The rainfall is averaged in space and time for a basin to obtain the hyetograph. We use the Road Research Laboratory Hydrograph method (the RRL method) to compute the storm runoff hydrograph for the basin from the hyetograph. A simulation result for a simplified atmospheric condition is presented. (Author abstract) 10 refs.

**092384 TWO PACKAGES FOR METEOROLOGICAL DATA PROCESSING AND RUNOFF SIMULATION FOR PERSONAL COMPUTERS.** This paper presents two packages designed to solve some of the most common problems involved in the analysis of a river catchment on a personal computer. The main operations performed concern preprocessing of raw meteorological data (to obtain time series of rainfall, snowfall and daily mean temperatures at different elevations), and simulation of the daily runoff from the catchment. Both packages have been developed at the Laboratorio di Informatica Ambientale e Territoriale (LITA) of the Politecnico di Milano, Italy. (Author abstract) 10 refs.

Gandolfi, C. (Politecnico di Milano, Milan, Italy); Pirovano, G.; Soncini-Sessa, R. *Environ Software* v 2 n 4 Dec 1987 p 192-198.

**092385 SIMULATION OF RUNOFF AND NITRATE LEACHING FROM AN AGRICULTURAL DISTRICT IN SWEDEN.** A twenty-year series of runoff and nitrogen leaching measurements from a cereal-dominated agricultural watershed in southern Sweden indicated a trend towards increased leaching. To investigate causal factors associated with the trend, two simulation models were used. Water and heat conditions were simulated with a physically based model. Simulated values agreed well with observed water flows, and no significant change in the water balance as a result of alterations in

land use were detected. Based on the simulated soil climate and data on land use, soil nitrogen dynamics were simulated with a nitrogen model. Model predictions were tested against leaching measurements. Alternative assumptions of 'fast' or 'slow' turnover of nitrogen in crop residues were tested. Model simulations of leaching agreed best with measured trends when a fast turnover rate of crop residues was assumed (i.e., < 50% of crop residue N was stabilized in humus). (Edited author abstract) 20 refs.

Jansson, Per-Erik (Swedish Univ of Agricultural Sciences, Uppsala, Swed); Andersson, Rune. *J Hydrol* v 99 n 1-2 May 15 1988 p 33-47.

**092386 URBAN RUNOFF SIMULATION MODEL.** Several rainfall-runoff simulations were conducted in order to determine the hydrologic response of the unit hydrograph to the impact of urbanization. A hydrologic model was formulated for an urban catchment located at Houston, Texas, using the kinematic wave model developed by the Hydrologic Engineering Center (HEC). The model was used to simulate various degrees of urbanization by allowing the percentage of watershed imperviousness and the channel roughness coefficient to vary from simulation to simulation. A system of regression equations was developed to quantify the impact of urbanization on the unit hydrograph. The equations were incorporated into the A&M Watershed Model and verified by modeling three test watersheds. (Edited author abstract) 20 refs.

**092388 EVALUATION OF PERMEABILITY OF PERMEABLE PAVEMENT FOR CONTROLLING STORM RUNOFF IN URBAN AREA.** One of the problems with which the urban storm runoff is confronted is the increase of the runoff water flowing into the rivers in the urban area. This increase of runoff water is caused by the development and urbanization around the river basin. This phenomenon in the increase of runoff water produces many problems in the storm water drainage. The permeable facilities for the storm water control are effective countermeasures for these problems. The values of permeability of the permeable pavement for controlling the storm runoff are evaluated on the basis of the research and studies in this paper. (Edited author abstract) 11 refs.

**092389 REGULATION OF STORM WATER POINT SOURCE DISCHARGES.** The National Pollutant Discharge Elimination System (NPDES) regulatory program is administered by the Environmental Protection Agency (EPA) to control point source wastewater discharges to waters of the U.S. Structuring regulations to

effectively deal with storm water has thus far been the subject of a 14 year controversy. The Water Quality Act of 1987 has been a two-edged sword for EPA's storm water program. Of primary importance is the notion that EPA is dealing with an infant program, and must, therefore, move cautiously towards the goal of effectively controlling storm water point sources. To that end, EPA should focus on qualitative information as a first step towards addressing the storm water problem in a practical and cost-effective, yet environmentally sound manner.
